ON Feb 19 an interesting lecture was delivered to the Royal Aeronautical Society by Prof Walter Georgii of Darmstadt and Mr Fritz Stamer on "Ten Years' Gliding and Soaring in Germany", and on "The Flying School at Wasserkuppe" The post-War restrictions on the use of power units for aircraft in Germany turned the attention of the younger generation in 1920 towards gliding as a substitute Since this form of flight depends on the use of slowly rising currents in the air, a practical glider is chiefly characterised by its small vertical component of velocity This is effected by reducing the total resistance, and the wing loading Thus a large span of good aspect ratio is adopted in order to give a small induced resistance. The body is closed and cantilever construction is used in order that there shall be no external bracing Launching is done by the usual method with a rubber cable, and the starting carriage is dropped In practice, in designing for low resistance, the structural weight is increased to a restricted degree and the result is to produce a medium heavy glider, with a margin of strength for high performance and for flying in gusty weather The additional weight gives greater air speed required for progress against strong winds and for passing rapidly through unfavourable belts of down winds For long distance soaring flight, a light compass and a Pitot tube are carried, but in research flights pressure gauges, inclinometers, and meteorographs are carried for recording air conditions

THE first impetus to gliding in Germany was given by W Klemperer in 1920, when he attained a glide of 2 minutes 22 seconds duration, traversing a distance of 1830 metres Progress came rapidly By 1922 gliding flights lasting more than one hour were attained Hentzen actually reached an altitude of 350 metres, remaining aloft for 3 hours 10 minutes Schultz, at Rossitten in 1924, recorded a flight lasting 8 hours 24 minutes, and in 1925, 14 hours 7 minutes This record was beaten in 1929 by Dinort with 14 hours 43 minutes It is characteristic of these flights that the best course between any two points is not necessarily the straightest, but may involve long detours in reaching up wind areas and lengthy soaring over a particular region to gain sufficient height The pilot, in fact, must fly on sound topographical and meteorological information

THE Essex Field Club commemorated the fiftieth anniversary of its foundation by a gathering on Feb 22, held in the Great Hall of the Municipal College, Stratford Among those who were present at the function were Lieut Col Sir David Prain (president elect of the Club), Sir Arthur Smith Woodward, Sir William Lister, Sir Henry Miers, Sir R Armstrong Jones, Prof J W Gregory, Prof E J Salisbury, Prof A G Green, Mr Reginald Smith, Mr J Ramsbottom, and Mr Arthur Cotton The Mayor of West Ham and the president of the Club, Mr D J Scourfield, jointly received the guests and in turn welcomed them to the function Speeches were made by the Right Hon Frances, Countess of Warwick, who made an eloquent appeal that the modern desecration of the countryside by petrol pumps and the like should be stopped by legislation, by Brigadier General Colvin, Lord Lieutenant of Essex, by Sir Henry Miers, by Sir Arthur Smith Woodward, and by Sir David Prain, each referring to those aspects of the Club's activities with which he was personally acquainted During the evening a conversazione was held, when there were many interesting exhibits of natural history objects and prehistoric relics, and an extensive series of topographical photographs and prints of Essex localities Lantern lectures were given by Mr William Glegg on "Some Features of Essex Bird Life", and by Mr S Hazzledine Warren on "The Land of Lyonesse in Essex", which were well attended Music was provided by a trio of ladies The Club's Museum, which adjoins the College, was closed to the general public on the occasion, and was inspected by the guests during the evening

The latest discoveries in the Antarctic reported in the *Times* are the result of the Norwegian expedition in the *Norvegia* Working westward from their discoveries of land adjoining Enderby Land, the Norwegians discovered a shallow bank, named after the ship, in about lat 67° S, long 32° E Bad weather and heavy ice made it impossible to find land which certainly must exist to the south The *Norvegia* therefore stood south west, and in lat 71° S, long 12° 29′ W, sighted a long chain of icebergs aground, and to the south of them shallow water extending to new land The north west point of this land is in lat 71° 26′ S, long 11° 31′ W From an aeroplane Capt Riiser Larsen and Capt Luetzow Holm charted this land for a few miles and saw it extending to the south west Part of the coast appears to be free from ice and part is faced by an ice cliff No peaks showed above the ice of the interior This new land is clearly an extension of Coats Land, which Dr W S Bruce discovered a little farther to the south west in 1904 There is little doubt that it is continuous with Enderby Land in the east

At a meeting of the Royal Society of Edinburgh on Feb 17, Prof Carl Størmer, of Oslo, delivered an address entitled "Do the Wireless Echoes of Long Delay come from Space outside the Moon's Orbit?" Prof Størmer mentioned first his mathematical researches on the aurora made in 1904, which gave among other things the result that streams of electrons sent out from the sun towards the earth could not penetrate into a certain definite region This region has the form of a tore or anchor ring which may be obtained by rotating an oval, which touches the earth's magnetic axis in its centre, round this axis This will be familiar to the readers of Nature from two letters published in November 1928 and January 1929 Prof Størmer then gave an account of the observations of long delayed wireless echoes made in Norway, England, and Scotland, and especially by a French expedition to observe the solar eclipse in Indo China in May 1929, where about two thousand echoes were observed, some of them coming 30 seconds after the signal with one third of its strength These echoes are explained by reflection of the wireless waves from currents and surfaces of electrons at the boundary or outside the above-mentioned toroidal region, and corresponding to distances from the earth several times as great as the moon's distance Prof P O Pedersen's reasons for adopting this explanation were also referred to

In his Friday evening discourse, delivered at The Royal Institution on Feb 21 on "Principles of Plant Breeding", Mr J B S Haldane said that the very numerous types of *Primula sinensis* in cultivation, including the new giant species or subspecies which is practically sterile with the ancestral form, have all arisen in cultivation in the last century They are determined by combinations of Mendelian genes, of which about thirty are known These have varied suddenly and spontaneously The laws governing their assortment in the progeny of hybrids are simple, but the result of new combinations is often unexpected. Thus, on dark stemmed plants, flowers which were expected to be a uniform blue proved to be mottled By the application of Mendelism the establishment of new races is greatly simplified, but, for the production of a first rate horticultural variety, selection is still needed The laws of inheritance in the giant subspecies, which has twice the original chromosome number, are more complicated than those enunciated by Mendel, and lead to quite different practical consequences A failure to realise these consequences has handicapped the practical breeder The application of these principles to other plants was briefly considered

A novel use of the mobility of radio communication will shortly be put into operation by the Egyptian State Telegraph Department Six radio sets mounted on three motor lorries have been ordered from the Marconi Company These sets are to be used as stations in areas not supplied by the land telegraph and telephone system This enables any place in a wide range of country on both sides of the Nile to be linked up at very short notice with the main telegraph system The motor lorries are of the six wheel type fitted with caterpillar attachments so that they will be equally mobile on hard or soft sand Each lorry will carry a medium wave half kilowatt telephone transmitter and a small portable short wave transmitter the power of which is a hundred watts The aerials are suspended from 70 ft portable masts Medium waves having lengths ranging from 600 metres to 2150 metres will be used, and also short waves having lengths ranging from 20 metres to 50 metres Egypt is a country in which, apart from the Delta, the towns and cities with their connecting railway and telegraph communications lie along a narrow strip of land bordering the Nile, with large areas of thinly populated or desert country on either side In these circumstances, these mobile radio stations should prove of value in providing extensions of the system either periodically as a regular service or in times of emergency

Engineer Rear Admiral W S Hill read a paper on powdered coal for ship propulsion to the North-East Coast Institution of Engineers and Shipbuilders on Feb 21, giving a review of the general position regarding the introduction of the use of pulverised coal afloat Particulars were given of some sixteen British and foreign vessels in which the boilers have been converted from hand firing to pulverised coal firing, or in which the boilers were originally fitted for burning pulverised coal The advantages claimed for pulverised coal are that it leads to a saving of labour approaching that saved by oil firing, that it improves the steaming of ships, and that there is a gain in overall efficiency Much depends on the actual power used for pulverising Two years ago, 25 h p per ton of coal milled was common, this figure, however, has been reduced to 14, and in a new mill about to be fitted afloat to 8 The burners have now taken a secondary place to the mill The general question of pulverised fuel burning, it may be added, is among the subjects now being investigated by the Fuel Research Board

THE Medical Research Council has appointed the following committee to advise upon the further investigation of pulmonary silicosis and of other pulmonary conditions associated with the inhalation of dusts arising from industrial processes Prof Arthur J Hall (Chairman), Dr A E Barclay, Mr J C Bridge, Prof S L Cummins, Prof E H Kettle, Dr E L Middleton (Secretary), Prof M J Stewart, Dr Cecil Wall The Committee will survey the present state of knowledge, will advise the Council upon new lines of inquiry that may be profitably pursued, and will assist in the supervision of such investigations as it may be decided to initiate or support The work will be directed particularly towards obtaining, in co operation with the Factory Department of the Home Office, more accurate knowledge of the causes and diagnosis of silicosis and of other industrial pulmonary disorders The need for better knowledge of these subjects has been emphasised by the recent Report of the Silicosis (Medical Arrangements) Committee, the recommendations of which to the Secretary of State for extended research work have been referred to the Council by the Home Office

THE second volume of the *Transactions* of the Seventh Congress of the Far Eastern Association of Tropical Medicine, held in British India in December 1927, of which the first volume was referred to in our issue of June 22, 1929 (p 954), has been issued (Calcutta Thacker's Press and Directories) It consists of 871 large pages, and comprises the proceedings of Sections III and IV Nearly a hundred papers, with the discussions to which they gave rise, are recorded in full, those of Section III deal with plague, cholera, dysentery, sprue and intestinal infections, bacteriophage, leprosy, tuberculosis, and bacteriology, while Section IV was concerned with typhus like diseases and leptospiræ, etc, protozoology, and malaria in all its aspects Malaria forms the subject of no fewer than thirty papers, leprosy takes ten, and five are concerned with the bacteriophage, an ultra virus parasitic on bacteria and provoking in them an extremely infectious disease which results in their destruction and solution The whole volume is important for all who are concerned with the cure, and especially the prevention, of disease in the tropics, and much of it is of high interest to scientific workers on more general lines The volume is well printed and the general get up excellent, it is illustrated by numerous maps and charts, as well as by twenty six plates, mostly in half tone, the reproductions of photographs which show the character of certain areas in Lower Bengal in relation to the prevalence of malaria being extremely good The editor, Lieut Col J Cunningham, is to be congratulated on the result of his labours

IN the past, submarine cables have played an invaluable part in submarine communications Until, however, the advent of 'loaded' cables, their use for telephone communication was very restricted Nowadays the distances which submarine telephone cables span are continually extending, and in a few years it seems probable that all the continents will be interconnected by a submarine telephone network We have received from Messrs Siemens Brothers and Co, Ltd, of Woolwich, a volume giving interesting particulars of some of the loaded submarine telephone and telegraph cables which they have put down In the early types of loaded cable the insulating material employed was gutta percha, but the development of submarine telephony led to the replacement of this material by paper, the resistivity of which is much greater A study of Heaviside's theories led to the adoption of the continuously loaded cable Commercial iron or silicon iron was used at first for the loading, but, as only low magnetising forces were obtainable, the increase in the speed was not great The discovery of permalloy, one of the nickel iron group of alloys which after appropriate heat treatment develops a very high permeability at a very low magnetising force and shows practically no hysteresis loss, greatly improved the quality of the loading It showed that submarine telephony over long distances was possible and greatly accelerated the speed at which submarine telegraph messages can be sent For example, in the Fanning Suva section of the Pacific cable, the speed has been increased to seven times that of the unloaded cable Particulars are given of the Isle of Man, Anglo French, Anglo Belgian, and Anglo Dutch submarine telephone cables

IN connexion with the Shannon hydro electric power station, it has been feared that the factories which will probably be built in the neighbourhood of Limerick will detract from the beauty of the west coast of Ireland At present the station helps to supply electric power to Dublin, but without the steam stations in Dublin the hydro electric power would be quite inadequate To supply power to Dublin from the station 120 miles away is not economical In our opinion, the water power available on the Liffey will sooner or later have to be harnessed for the benefit of Dublin, and possibly also the huge amount of peat available in the Bog of Allen will have to be utilised The natural place to utilise the Shannon power is along the west coast As the population increases, it is necessary to provide houses and factories for them, and many of the beauty spots will suffer In *Distribution*, the journal of Henley's Telegraph Works, for February, an account is given of the Cadbury Fry Pascall Ltd factory which was built seven years ago at Claremont, Tasmania The factory is built near the sea and is surrounded by picturesque mountains, including Mount Wellington The buildings are lighted by more than 800 windows and the floor space is 120,000 square feet A model garden village has been laid out for the workers, the cottages each containing two or three bedrooms and two sitting-rooms Tennis courts, golf links, and everything that human ingenuity can do has been done to make the workers contented The 85 motors and 12,000 lights are supplied with power purchased from the hydro-electric system Special shower baths and dressing rooms are provided for the workers, and electric lifts transport passengers and materials to the upper floors Whenever possible, Australian raw material and machinery are used There are many suitable

sites for similar factories within fifty miles of Limerick

In the second Rickman Godlee lecture delivered at University College, London, on Nov 7 last and recently published by the College, Viscount Grey of Fallodon gave a charming account of "Natural History, the Pleasure and Purpose of Observation" In simple language, more expressive than technicalities could ever be, and with many touches of humour, he pointed out the need for accuracy and caution in observation, and at the same time the danger of sterility which lies in over caution His speech itself expressed his own pleasure in the study of Nature, and this he visualised as having four aspects the pleasure in common things; the pleasure in observing changes caused by the change of the seasons and the variety of light, the pleasure of noting the recurrence of things which come round regularly, for which we have learned to care, and last, the interest in seeing something rare The address (which has been published by the College at 1s) should become a text for the teacher of nature study in schools, for if nature study could but open the eyes and minds of youth to these beauties of sense and thought, it would fulfil its main purpose of adding to the fullness and happiness of life

Among recent accessions to the British Museum (Natural History) are six photographs of East African elephants taken by Mr Marcuswell Maxwell and presented by the proprietors of the *Times* Of the collection of birds purchased for the Museum, some 300 of them, of about eighty different species, were collected by Mr G L Bates during a trip in 1928 in a part of the interior of West Africa through which no ornithologist has previously travelled The Entomological Department has received a collection of 1362 tiger-beetles from all parts of the world, presented by Mr H E Andrewes, and a collection of Coleoptera and Hymenoptera from the Algerian Sahara, numbering 1224 specimens and including the types of several new species, from Dr Ernst Hartert The most interesting acquisitions to the Department of Geology are a complete *Ichthyosaurus* on a slab of Lower Lias limestone from Street, Somersetshire, and a large collection of Permian echinoderms and brachiopods, Triassic ammonites, and Tertiary gastropods and lamellibranchs from the island of Timor. The collection of minerals has received gifts of three new species bismutotantalite, from Uganda, from the Director of the Geological Survey of Uganda, probertite, a borate mineral from California, from Prof F H Probert, and larnite, from Larne, Co Antrim, from Dr C E Tilley Recent acquisitions for the general library include Carlo Ruini's "Anatomia and Medicina Equorum nova", 2 volumes, Franckfurt am Mayn, 1603, the astronomer Olof Peter Hiorter's "Almanach för skott-ahret . 1744", an official Swedish almanack, about three inches square, with an article by Linnæus on Swedish plants, one of the only two copies known, and a copy of the anonymous skit on monasteries by the great mineralogist, Baron Ignaz von Born, in the style of a Linnæan zoological dissertation, entitled "Joannis Physiophili Specimen Monachologiæ methodo Linneana Augustæ Vindelicorum, 1783", one of three copies known

Baron Koi Furuichi, of Tokyo, has been elected an honorary member of the Institution of Civil Engineers

An earthquake was recorded at Kew Observatory on Feb 23 The first impulse was received at 18 h 23 min 50 sec G M T The epicentre was off the south of Greece near lat 37° N, long 23° E The shock was of about the same intensity as that which occurred on Feb 14 in the same region and caused considerable damage in Greece and Crete

Prof W E Gibbs, Ramsay professor of chemical engineering at University College, London, will deliver an address before the Institution of Chemical Engineers on "The Formation and Growth of Crystals", in the rooms of the Geological Society, Burlington House, London, W 1, on Mar 5, at 8 p m All who are interested in the subject are invited to attend

Recent promotions and transfers in the Colonial Agricultural and Forestry Services include the following Mr D C Edwards, agricultural instructor, Sierra Leone, to be agricultural officer, Kenya, Mr C B Taylor, superintendent, Agricultural Department, Nigeria, to be botanist, Nigeria, Mr D B Palmer and Mr L R Swindells, to be produce inspectors, Nigeria, Mr J C Rammell, assistant conservator of forests, Kenya, to be senior assistant conservator of forests, Kenya

At a meeting of the Geological Society of London, held on Feb 21, the following officers and new members of council were elected *President* Prof E J Garwood, *Secretaries* Mr W Campbell Smith and Prof W T Gordon, *Foreign Secretary* Sir Arthur Smith Woodward, *Treasurer* Mr F N Ashcroft, *New Members of Council* Prof P G H Boswell, Prof C G Cullis, Mr J F N Green, Sir Albert Ernest Kitson, and Dr Bernard Smith

At the annual general meeting of the Quekett Microscopical Club, held on Feb 11, the following officers and new members of the committee were elected *President* Mr John Ramsbottom, *Hon Treasurer* Mr C H Bestow, *Hon Secretary* Mr W S Warton, *Hon Reporter* Mr A Morley Jones, *Hon Librarian* Mr C S Todd, *Hon Curator* Mr C J Sidwell, *Hon Editor* Mr W S Warton, *New Members of Committee* Mr E A Robins, Mr F W Chipps, Mr J J Jackson, and Mr C Harvey

Applications are invited until Oct 11 next from British subjects of either sex for the Smithson Research Fellowship, which has been established under the bequest of Mr E W Smithson for research in natural science, with a view to the discovery of new laws and principles. Normally the research work of the holder of the fellowship will be carried out in the University of Cambridge The appointment will be for four years in the first instance, with possible renewals up to eight years The yearly stipend for the first two years will be £800 Copies of the regulations governing the fellowship, and forms of application, may be obtained from the Assistant Secretary of the Royal Society, Burlington House, Piccadilly, W 1

A COMPREHENSIVE and attractive tour of Great Britain and Northern Ireland has been arranged to follow the World Poultry Congress to be held at the Crystal Palace on July 22–30 The tour, which is limited exclusively to delegates, will extend from July 31 to Aug 11, and has been designed to combine a visit to places of interest to agriculturists in general and poultry farmers in particular, with a run through the beauty spots and historic centres of England, Scotland, Wales, and Ireland The project has been assisted by the Irish Free State, which has organised a tour to be taken *en route* Governments, municipalities, and other bodies will entertain the visitors The cost of the tour will be twenty-five guineas

THE Ministry of Health has issued a memorandum on the treatment of tuberculosis (*Memo* 131 B/T), being an analysis of work done during the year 1928 under the scheme of local authorities for the treatment of the disease The returns include the death rates from tuberculosis per million of population in different areas, which show considerable variations The counties with the highest rates are Durham (1059) and Cornwall (1032), while Rutland has the lowest (501) Of the county boroughs, South Shields has the highest rate (2135) and Southport the lowest (631) Gloucester and Canterbury, which might be expected to be very similar, have rates of 689 and 1235 respectively Of Metropolitan boroughs, Hampstead has the lowest rate (536) and Finsbury the highest (1639), the City of London being second with 1537 The average rate for all England is 924 Another memorandum (*Memo* 146/T) details changes necessitated by the Local Government Act, 1929, in the arrangements for the treatment of tuberculous ex-service men so far as chargeable to the Ministry of Pensions

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant bacteriologist in the Department of Pathology and Bacteriology of the University of Sheffield—The Registrar, The University, Sheffield (Mar 3) A head of the Chemistry and Industrial Chemistry Department of the Cardiff Technical College—The Principal, Technical College, Cardiff (Mar 8) A resident radiologist at St Bartholomew's Hospital, Rochester—The Secretary, St Bartholomew's Hospital, Rochester (Mar 11) A lecturer in mining subjects at University College, Nottingham—The Registrar, University College, Nottingham (Mar 15) A Montague Burton professor of industrial relations at the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (Mar 15) A chemist in the Cereal Division of the Experimental Farms Branch, Department of Agriculture, Canada—(Particulars and application forms from The Secretary, High Commissioner for Canada, Canada House, Trafalgar Square, S W 1) The Secretary, Civil Service Commission, Ottawa, Canada (April 17) A professor of engineering at University College, Southampton—The Registrar, University College, Southampton (April 22) An assistant professor of physiology and pharmacology in the University of Alberta—The Secretary to the Board of Governors, University of Alberta, Edmonton, Alberta

Our Astronomical Column.

New Comet 1930a —The first cometary discovery of 1930 appears to have been made independently in two places (1) by Mr L Peltier, at Delphos, Ohio , and (2) by Drs Schwassmann and Wachmann at Bergedorf The following observations have come to hand from the I A U Bureau, Copenhagen, the second being made by Prof G van Biesbroeck

U T	R A 1930 0	N Decl 1930 0	Place
Feb 18d 22h 29m 4	9h 39m 40s 27	34° 46′ 11″	Bergedorf
20 4 19 9	9 22 38 93	40 21 55	Yerkes

The magnitude was given as 10 on Feb 18, and 11 on Feb 20 The deduced daily motion is $-13\frac{1}{4}$ min , North $4\frac{1}{2}$° The comet is probably fairly near the earth, from its very rapid motion Owing to its high north declination, it is observable throughout the night Mr Peltier was the co discoverer with Mr Wilk of Comet 1925 XI

The following elements and ephemeris of Comet 1930a, computed by Mr J P Möller, Copenhagen, have been telegraphed by the I A U Bureau

$$\begin{array}{ll} T & 1930 \text{ Jan } 15\ 686 \text{ U T} \\ \omega & \left.\begin{array}{l} 325^\circ\ 10' \\ 147\quad 33 \\ \ \ 99\quad 55 \end{array}\right\} 1930\ 0 \\ \log q & 0\ 03655 \end{array}$$

(with Ω on the second and ι on the third element line)

Astro-Photography of the Future —Dr G W Ritchey contributes another article, in continuation of that referred to in NATURE of Feb 1, p 180, to *L'Illustration* of Jan 18 Several further photographs of nebulæ, both diffuse and planetary, are beautifully reproduced , all except one of these (the obscure nebula south of ζ Orionis, photographed by Duncan) are taken from his own plates obtained with the 60 inch reflector at Mount Wilson Observatory Dr Ritchey gives a brief history of our knowledge of nebulæ, and describes with a certain amount of detail the particular objects illustrated It is not clear, he says, why the chief observatories of the world, which are richly endowed, and the principal institutions formed for the advancement of science, do not unite to establish a large photographic telescope at some carefully chosen, elevated, and unpopulated place, in latitude about 25° S , where the star clouds and nebulæ of the Sagittarius region—which certainly form the most important and interesting part of the Milky Way and have been comparatively unexamined by powerful modern instruments owing to the situation of the latter in northern latitudes—could be effectively investigated If some friend of astronomy would provide the funds for such an undertaking, unsuspected and incredible discoveries would be made, to the great profit of science and education The resources and possibilities of celestial photography have scarcely begun to be explored Vital details have been almost totally neglected When they are given the attention they deserve, a new celestial photography will be born, and the results will be incomparably more useful and important for thinking humanity than those obtained up to the present

Research Items.

A Communal House on Little Andaman.—The supplement to *The Indian Antiquary* for January is an instalment of Sir Richard Temple's "Remarks on the Andaman Islanders and their Country", which consists of extracts from a report by Mr P Vaux on a reconnaissance in Little Andaman on Jan 25–Feb 4, 1902 Mr Vaux had been detailed to operate against the Jarawa This tribe lived in the then untouched forests of Little Andaman, and had not been brought under the control of the administration They indulged in periodical raids, in which murder regularly played a part Their exact location was not known, and they had proved both elusive and unapproachable Shortly after the date of this report, another punitive expedition was successful in dealing with them, but Mr Vaux was killed in the attack In this extract he describes several camps of the Jarawa, empty when he reached them, and a large communal house or camp, situated at the top of a steep hill, and approached by seven paths It was in a clearing which had been carefully prepared Several large trees had been felled, not only for space, but also to give outlook Two of the entrances had sloping log platforms to serve as look outs, and probably when the tribe was in residence (it left the camp for small hunting huts in the dry season) each entrance was guarded by similar platforms The hut was roughly oval, being sixty feet by forty feet in dimension, with a circumference of fifty four yards Seven stout posts in the centre supported the roof, and from the top of the roof between these posts were 250 pigs' skulls neatly fastened up in a basket Below the skulls was a big fireplace, while round the walls were the smaller family fireplaces, probably a dozen in number when the hut was full Each fire place consisted of four stakes driven in the ground About three feet from the ground a piece of matting fastened to the stakes formed a shelf for the meat The thatching was decorated with hundreds of fan-like bunches of leaves, and honey pots, baskets, unstrung bows, leaf water vessels, etc, hung from the roof

A Statistical Measure of Civilisation.—Dr R M Harper, in an article on some demographic characteristics of American educational centres in the February *Scientific Monthly*, describes an attempt to measure the degree of civilisation in twenty five towns in the United States in which a university dominates the life of the community Towns with large factories are excluded, and none is chosen with less than 80 per cent of white population In the average of the twenty three towns, adult illiteracy is 2 18 per cent, compared with 5 50 for the urban population of the whole country Persons per family average 3 86, compared with 4 24, children average 1 38, compared with 1 58, and males represent 47 2 per cent of the population, compared with 50 1 in the urban population as a whole This last figure is the most striking In all the towns the percentage of females is higher than that of males, while the proportions are reversed in nearly all the States in which the towns lie It should be noted that few of the actual students in the colleges come into the figures since the census enumerates them in their homes Dr Harper discusses the value of the different orders of statistics which he uses, and lays stress particularly on the sex ratio and the illiteracy count

Food of Grasshopper Mice.—Examination of the stomach content of birds has become a standard method of assessing their food, but the method has seldom been applied to mammals, perhaps because the same doubt has never arisen as to the usefulness or harmfulness of any particular species We would direct attention, therefore, to a good example of mammalian stomach content assessment, which, most unusually, sets the stamp of good-conduct upon one of the rodents Vernon Bailey and Chas C Sperry, in a thoroughgoing account of the life history and habits of the genus *Onychomys*, record analyses of 96 stomachs (U S Dept Agr, *Tech Bull* No 145, November 1929) The materials found are specified in detail and the numbers of individuals of, say, grasses or insects, are given This method is much more satisfactory than the volume percentage method which has been adopted in the United States and elsewhere for the recording of the food of birds The results were that eight ninths of the food of *Onychomys* were found to consist of animals, mostly crickets, grasshoppers, caterpillars and moths (55 8 per cent), and beetles (20 73 per cent) Cultivated grain comprised less than 5 per cent of the food, and as it consisted mostly of wheat eaten in July, it was probably waste It is seldom that a rodent does anything but harm to agricultural interests, but here is a little group of species and varieties which are economically beneficial

A Rare Cephalopod.—Mr G C Robson has described and discussed a new species of *Melanoteuthis* collected by Beebe during one of the *Arcturus* voyages (1926), from the deep waters near Cocos Island (E Pacific) ("On the Rare Abyssal Octopod *Melanoteuthis beebei* (sp n) A Contribution to the Phylogeny of the Octopoda" by G C Robson, *Proc Zool Soc London*, Oct 1929) Two specimens were obtained, and these proved so interesting that a special account is given of them apart from Dr Beebe's other cephalopods The examination of the present species throws new light on the systematic position of the genus and probably of the family Vampyroteuthidæ to which it belongs *Melanoteuthis*, although specialised in some respects, has several features which suggest that in it we see the most primitive octopod and that it retains characteristics of the common stock from which the Decapoda and the Octopoda arose Chief among these is the presence of filaments contained in the velar pouches which Joubin (1928) regards as a vestigial pair of arms —a view fully confirmed by Mr. Robson There are several distinctive features The nervous system is diffuse, the suckers pedunculate, there is a valve in the funnel and a median plate like shell rudiment, whilst there is no white body characters not found in the Octopoda but resembling the Decapoda The radula is simple and undifferentiated as in most primitive Decapoda and in *Argonauta* There are certain features which are found in the Cirroteuthidæ and some not found in the Cirroteuthidæ but found in other octopods The author suggests dividing the Octopoda into three sub orders—Vampyromorpha, Cirromorpha, and Incirrata, *Melanoteuthis* belonging to the first

Opium in the Poppy.—It was at one time thought that the elaboration of active principles in medicinal plants underwent either qualitative or quantitative attenuation when the plants were cultivated away from their natural habitat Thus, in his "Farmacopea riformata" (Venice, 1655), Quercetano states that, when transplanted into improved soil and carefully cultivated, the opium poppy becomes less poisonous This statement, often repeated, has been shown, by long series of experiments in Asia and in Europe, to be without foundation A similar conclusion is arrived at from the results obtained in the Royal Botanic

Gardens at Naples According to Cavara and Chistoni, in a paper published in the *Rendiconti dell' Accademia delle Scienze Fisiche e Matematiche di Napoli* for 1929, the morphine content of the poppy was raised, by improved cultivation and selection, from 5 46 per cent in 1923 to 10·11 per cent for the white, and to 12 14 per cent for the black poppy in 1924 Experiments on the hybridisation of the two varieties show that the opium obtained from hybrids of the fourth generation gives a high percentage of morphine The diminishing morphine content in the opium content of successive incisions is also confirmed Moreover, the occurrence of rain either during or after the incision exerts a peculiarly harmful effect, since not only does the opium lose its viscosity and consistency, but its morphine content is also greatly reduced

Indian Liverworts —The only comprehensive work upon Indian Liverworts so far has been the paper by Mitten in the *Jour Linn Soc*, **5**, 1860 Many more species have since been described, especially by Stephani, but there is much room for an illustrated account of Indian liverworts The first step towards such a publication has been taken in the issue by the University of the Punjab, Lahore, of Part I of the "Liverworts of the Western Himalayas and the Punjab Plain", by Shiv Ram Kashyap This volume deals with the Anthocerotales, Marchantiales, Sphaerocarpales and the Anacrogynous Jungermanniales The Acrogynae will be dealt with in a second volume The author hopes that later it may be possible to issue an account of the group for the whole of India, but large collections must first be made in the eastern Himalayas and South India In this work indigenous species receive fuller treatment and more figures A brief discussion of the area studied and the habitat of the liverworts is given in the introduction, whilst a full glossary and a key to the genera precedes the systematic description of species

Sylvicultural Research in India —The paper on "Sylvicultural Research in India, its Organisation, Problems, and Methods", by H G Champion, in the second issue of vol 3 of *Forestry*, should make a wide appeal to all professional foresters of the gazetted ranks and to all interested in technical forest research throughout the British Empire It may be contended without fear of contradiction that it would have proved impossible to write this paper a decade ago, and at the present day it could have only been written, for the Empire, by a research officer of the Forest Research Institute at Dehra Dun with all the data of the past history of sylvicultural research in India at his disposal, and the wide knowledge possessed by the author himself It is impossible here to do more than direct attention to this valuable paper Mr Champion discusses the present division of the work of research between the central sylviculturist at Dehra Dun and the provincial research sylviculturists who have been appointed in all the provinces of India (and Burma) with the exception of Bombay and the Punjab He also points out the necessity of selecting for such posts the best available officer and not the man who has shown himself a failure in executive or administrative work He then discusses in detail the lines upon which research work is now carried out and the enormous number of problems which such work has disclosed as awaiting solution That astonishing progress has been made during the past quarter of a century in a subject which was almost a sealed book thirty years ago the paper provides ample proof It is with no idea of minimising the value of *Forestry* to express the hope that Mr Champion's paper may be republished in such a form that it may become available to a wider circle of readers

Jan Mayen —Norwegian interest in Norway's new arctic territories in Spitsbergen, Bear Island, and Jan Mayen, is shown in the many valuable publications of the Svalbard og Ishavs Undersökelser, which appear at frequent intervals under the collective title of *Skrifter om Svalbard og Ishavet* A more popular series appear as *Meddelelser*, some of them extracted from other publications One of the latest is a small pamphlet on Jan Mayen (*Norsk Geografisk Tidsskrift*, **2**, 7), which gives a summary of the structure and climate of that island, beside a full account of its history and the seal fishing in the vicinity The paper is chiefly valuable for its full bibliography of Jan Mayen

New Cretaceous Ostreidae from Texas —Two new species of Ostreidae from the Austin Chalk of central Texas described by L W Stephenson (*Proc U S Nat Mus*, vol 76, art 18) are of particular interest, one, *Ostrea centerensis*, n sp, because it has been found abundant in a zone only a foot or two in thickness without trace of further occurrence in the beds above or below The author suggests it was a temporary immigrant from the tropical seas of the Caribbean region The other, *Exogyra tigrina*, n sp, is remarkable in that it offers one of those rare cases of the preservation of colour markings in a fossil These take the form here of brownish, radiating colour bands alternating with grey bands It recalls the similar markings on the European cretaceous *Gryphaea columba*, Lamk, cited by the late R B Newton (*Proc Malac Soc*, vol 7, p 283) when treating on the subject generally, a paper Mr Stephenson has not apparently seen

Continental Connexions in the Cretaceous —In the *Amer Jour Sci* for January 1930, Prof C Schuchert discusses the important memoir on the dinosaurs and other reptiles of the Cretaceous of the Argentine recently published by F von Huene (*Anales del Museo de la Plata*, vol 3, series 2a, p 196, 1929) Von Huene's hypothesis of an Asiatic Polynesian South American land bridge across the southern Pacific raises again the very difficult problem of how to explain the disappearance of such extensive land bridges Schuchert suggests an alternative and more probable route for Asiatic migrations through Australasia to Antarctica and thence to South America or Africa Von Huene states that South America is the home of the specialised marsupials, and that from there representatives of both diprotodonts and polyprotodonts spread to Australia but not to New Zealand Previously the monotremes and allotheres had spread from south eastern Asia to the Australian region, and from there the allotheres reached South America, which became a new development centre for them These and many other affinities, some of which are summarised in the paper, between the organic worlds of South America and the lands to the west, cannot be understood without the assumption of former land connexions, particularly in the Cretaceous At that time the larger faunal elements might have advanced by stages from Asia to South America, but, at the latest in middle Tertiary times, the continuity of the lands most have been broken through In view of Schuchert's iconoclastic attitude towards continental drift hypotheses, it is interesting to notice that he fully recognises the geophysical difficulties in the way of assuming the foundering of land bridges, and that in seeking for a connexion between South Africa and Antarctica he is not averse to admitting a certain amount of drift to the north on the part of Africa

Raman Effects in Liquids.—The issue of the *Physikalische Zeitschrift* for Dec. 1, 1929, contains a description of a new method of observing the Raman effect in liquids by Dr. R. Bär, of the University of Zurich, which gives more intense lines than previous methods and has cleared up some of the uncertainties with regard to the effect in benzol. The liquid is contained in a glass tube about a metre long, one end of which is widened into a cone closed by a glass plate, and the other drawn off sideways to a point to prevent reflection at the end. The light from a mercury lamp falls on the base of the cone and is focused by lenses at a point in the liquid near the apex of the cone, and the effect is observed from the side by means of a small mirror attached to the base of the cone at an angle of 45° to the axis of the tube. Evidence of the existence of increases of wave numbers by 605 and 990, that is, in the anti-Stokes law direction, and of decreases 2947 and 3179, was found in benzol, but none for the existence of the decreases 266, 1360, 1479, and 2630.

Mass-Spectra of Mercury, Krypton, and Xenon.—An investigation of the positive rays of mercury, krypton, and xenon, in which the relative abundance of the isotopes of these elements has been found by photometry of their lines in mass spectra, is described by Dr. F. W. Aston in the February number of the *Proceedings of the Royal Society*. Whilst mercury has been found to have an atomic weight in close agreement with the accepted value of 200·61, the number calculated from the percentage abundance of the seven isotopes being 200·62(6) ± 0·05, the results for krypton and xenon are not in accord with older determinations. Their atomic weights as deduced from their densities are 82·92 (Kr) and 130·22 (Xe), whilst those calculated from the mass spectra are 83·77 ± 0·02 and 131·27 ± 0·04. The xenon used for the density determinations had been examined by Dr. Aston with a mass spectrograph in 1922, and was then shown to be free from krypton, the only likely impurity, so that it seems possible that the reduction of the density data may have been incorrectly made. Dr. Aston mentions that the auxiliary information that is required for the accurate deduction of an atomic weight from a density is less well known than could be desired for these two inert gases, and suggests that the density determinations should be repeated, preferably with a microbalance at low pressures.

Transparent Window Glasses.—Since the discovery that ultra-violet light of wave-lengths close to 302×10^{-7} cm. would cure rickets in children, special window glasses transparent to these rays have been introduced, and as there were indications that they lost some of their transparency with use, the U.S. Bureau of Standards has investigated the properties of a number of these glasses. *Research Paper* 113, by Messrs. Coblentz and Stair, collects the results obtained. Sunlight at Washington at midday in summer contains 0·3 per cent of the curative rays, and of this the glasses in the market at the beginning of 1929 would transmit when 0·23 cm. thick and quite new from 63 to 48 per cent. After exposure to sunlight for a summer or to the light from a quartz mercury arc for 10 hours, their transmission had fallen to 49 and 23 per cent respectively, and remained approximately at those values on further exposure. A much more serious reduction is produced if the surfaces of the glass are not kept clean and free from dust.

Formation of Nitric Oxide.—Following on a recent statement that the yield of nitric oxide formed in the arc is increased if carbon dioxide is present, Tartar and Hoard, in the January number of the *Journal of the American Chemical Society*, describe some careful experiments on this reaction. They find that, with currents of 65 milliamp., only one-sixth the concentration of nitric oxide is produced from a mixture of nitrogen and carbon dioxide as is produced from air, and the effect of reduced pressure is very slight. An increase in the yield was obtained by increasing the current by 50 per cent. The authors conclude that the reaction offers little promise as a method of nitrogen fixation in the arc.

Measurement of Coal Dust Inflammability.—One of the gravest hazards of coal mining—the coal dust explosion—is now recognised and countered by the process of stone dusting the underground passages. Coals differ in inflammability, and in order to apply the remedy rationally a method has been devised which is described in the *Safety in Mines Research Board Paper*, No. 56, by A. L. Godbert and R. V. Wheeler (London: H.M. Stationery Office), whereby this property can be gauged in the laboratory. It consists in determining the proportion of inert dust necessary to suppress inflammation when small quantities are blown by oxygen through a heated tube. The results are comparable with those given by trials in an explosion gallery. By means of the test it was shown that the inflammability roughly increased with the content of volatile matter of the coal and more precisely was associated with the reactivity of the ulmin contents.

Ignition of Gases by Electric Spark.—The problem of discovering the exact process which takes place when a combustible gas is ignited by an electric spark is one of great importance in motor car engineering. There are, however, so many variables to be considered when a magneto is employed for producing the spark that little progress has been made towards getting a solution. A paper by Messrs. Terada, Tumoto, and Yamamoto on the difference in the behaviour of different parts of a 'three-part spark' in igniting combustible gas mixtures, which is published in the *Scientific Papers of the Institute of Physical and Chemical Research, Tokyo*, p. 132, 1929, is of value in this connexion. They experiment on the spark obtained between equal spheres when the lead of the positive electrode is earthed or provided with a corona leakage from a needle point. The electricity was continually applied by a statical machine. In this case, when the spark gap is about three times the diameter of either sphere, it is divided into three distinct parts which are quite different from one another and are called the positive, middle, and negative parts. The middle part is the most luminous, and its spectrum shows the head of the second positive band of nitrogen superposed on a continuous spectrum. The other parts give the ordinary spark spectrum of air together with some metallic lines. Tests were made to find out the igniting power of different parts of the spectrum. A fine jet of the combustible gas being experimented on was directed towards different parts of the jet and the number of ignitions that followed was noted. The frequency of the ignitions was much the greatest in the middle of the arc and was least at the junctions of the middle part with the positive and negative parts. Since the duration of the discharge in the middle part of the arc was only about a tenth of the duration of the positive and negative parts, it was not a cumulative time effect. There is a decided difference in the mode of excitation of the molecules in the different parts of the arc, and this has a great effect on its igniting properties.

Progressive Chemistry

THE *Journal of Chemical Education*, a beautifully printed and illustrated monthly magazine of some two hundred pages, conveys a striking and even startling impression of the popularity and progress of chemical studies in the United States. The journal, which costs two dollars fifty cents per annum, is the official organ of the Division of Chemical Education of the American Chemical Society, and its aim may be expressed in terms practically identical with those which are applied in the January issue to the closely related Chemical Foundation Inc., that is, "the advancement and maintenance of chemical education in the United States to the plane where we shall have not only the best chemistry teachers and methods of teaching this science in the world, but also have the most enlightened lay people who will appreciate the importance of the application of chemistry in all phases of life and industry."

The staff of the journal includes six departmental editors and more than sixty contributing editors; in addition to the latter there are sixteen abstractors. Among the dozen foreign editors we notice the names of Sir James Irvine (St. Andrews), Prof. F. G. Donnan (London), Prof. K. Freudenberg (Heidelberg), Prof. E. Cohen (Utrecht), and Prof. W. D. Treadwell (Zurich). The thorough way in which the Division of Chemical Education of the American Chemical Society has set about its duties is evident from the lists of committees, members of the Senate of Chemical Education, and local organisations operating in the various States. The twelve committees upon the current list are concerned with such subjects as aids to visual instruction in chemistry, chemical education of the non-collegiate type, correlation of high school and college chemistry, labels, professional spirit among high school teachers, research problems, and women's club study course in chemistry.

The editorial article of the January issue contains some interesting references to Benjamin Silliman (1779–1864), the first professor of chemistry at Yale, who took up the duties of the chair in 1804. "America's first great scientific publicist", in his early days at Philadelphia, was acquainted with Hare and Priestley the chemists, Wistar the anatomist, Barton the botanist, and Seybert the mineralogist; he therefore links these names with those of his own eminent pupils of a later age, among them "Dana, world renowned geologist and mineralogist; Brush, whose exhaustive mineralogical chemical studies are authoritative everywhere; Johnson, pioneer leader in chemistry applied to agriculture; Willard Gibbs, first among physical chemists of modern times; T. Sterry Hunt, profound in chemical philosophy and theory." There are articles on the tung oil tree (with some good coloured plates), the teaching of electrochemistry (a symposium presented before the American Electrochemical Society at Toronto, in 1929), educational activities of Mellon Institute, and chemical warfare.

Among other features, there are contests for students, notices of new books and scientific articles in magazines, and illustrated abstracts of interesting papers from current chemical and educational journals—including a section entitled "Keeping up with Chemistry." "One of the hardest and most disappointing things is to endeavour to retain an active interest in chemistry after one has graduated," is the complaint of a writer in the December *Alchemist*, the official organ of the Glasgow University Alchemists' Club. This very real difficulty would be overcome if chemists in Great Britain could develop sufficient enterprise to publish a British counterpart to the lively and stimulating American *Journal of Chemical Education*, which is now in its seventh year.

Stellar Velocities and Stellar Physics

AT the annual meeting of the Royal Astronomical Society on Friday, Feb. 14, the president, Dr. A. C. D. Crommelin, delivered an address on the work of Dr. J. S. Plaskett, director of the Dominion Astrophysical Observatory, Victoria, B.C., to whom the Gold Medal of the Society has this year been awarded "for his valuable observations of stellar radial velocities and the important conclusions derived from them." The award, said Dr. Crommelin, was made "not for any single outstanding result, but in recognition of the high merit of a long series of researches, extending over a quarter of a century, and marked throughout by a painstaking striving after the highest accuracy attainable, combined with an alertness in discerning problems of stellar motion and stellar physics to which the powerful observational means available might most suitably be applied".

Dr. Plaskett's astronomical career began in 1905 at the Ottawa Dominion Observatory, where he was placed in charge of the Department of Astrophysics. His early work included the determination of stellar radial velocities for various purposes, but the instruments at his disposal would not permit of an extension of the work beyond stars of the fifth magnitude. It soon became clear to him that the greatest need in this work was the examination of fainter stars, and the possibility of obtaining a telescope of larger aperture than those he had up to that time employed began to occupy his thoughts. During a visit to Mount Wilson in 1910 to attend a meeting of the Solar Union, the desire to obtain such an instrument was greatly intensified by an appeal from Prof. Campbell for co-operation in determining the radial velocities of the fainter stars. Dr. Plaskett conceived the idea that Canada might distinguish herself among the nations by erecting a giant reflector for spectroscopic research, and on returning to Ottawa he laid his scheme before his director, Dr. W. F. King, who endorsed it with enthusiasm. Mainly through Dr. Plaskett's efforts, the 73-inch telescope—the largest in the British Empire and the second largest in the world—was erected at Victoria, and he was appropriately appointed as the first director of the new observatory established at the same time.

Of the large amount of important work which has been done both by Dr. Plaskett himself and by assistants under his direction, arising from the extended programme of radial velocity determinations thus made possible, the outstanding results relate to the study of the high temperature *O* type stars, the character of the interstellar calcium cloud, and the rotation of the galaxy. Among the *O* type stars, particular interest attaches to 'Plaskett's star', a binary the components of which are respectively at least 86 and 72 times as massive as the sun. These are easily the largest figures for stellar masses so far found in our sidereal system. Dr. Plaskett assumed, in the absence of evidence to the contrary, that the stars, as seen from the earth, do not eclipse one another in their mutual revolution, but Dr. Crommelin gave reasons for doubting this. If it should be established from variation of the light that eclipses take place, more precise values of the masses will be obtainable.

The systematic investigation of the 'stationary' ionised calcium lines in the spectra of hot stars which Dr Plaskett carried out led to the first clear demonstration that the material responsible for these lines had no motion with respect to our system of stars His earlier suggestion that it was originally discharged by the hot stars and came to rest some distance away from them probably needs modification in view of the evidence for Eddington's hypothesis that the matter is distributed throughout interstellar space, and indeed Dr Plaskett, in a very recent paper, has himself given some of the strongest evidence for the latter view by showing, from the consideration of three separate groups of stars, that the average distance of the cloud is half that of the stars in the spectra of which its lines appear It must be remembered also that Eddington's work in this connexion would not have been possible but for the thoroughness and accuracy of Plaskett's original investigation

The idea that the galaxy is rotating is not a new one, but the evidence for some former ideas on this matter is now known to be spurious The subject has lately come to the fore again through the realisation that our stellar system is probably a spiral nebula, and therefore is in all probability rotating in the manner which the appearance of those bodies forces us to admit Specific evidence for the rotation recently came from Oort and Lindblad, and Dr Plaskett at once perceived that his radial velocity measurements could throw an important light on the matter He analysed the motions of the distant stars—those of types *B* and *O*, of which he had made a special study—and was able to show that they gave clear indications of rotation about a centre in galactic longitude 324 5°, which agrees with the position given by Oort and also with that found by Shapley for the centre of the galactic system from totally different considerations based on the distribution of globular clusters The centre of the galaxy is near the junction of the constellations Sagittarius, Ophiuchus, and Scorpio, in a 'rift' between two branches which is probably caused by obscuring matter hiding from us what would otherwise be the brightest part of the Milky Way Dr Plaskett's contributions to the elucidation of this problem have been characterised by the solidity and thoroughness which he has shown throughout his career, and his results, however their interpretation may vary, are permanent

Dr Plaskett, who has been invited to give the George Darwin lecture of the Royal Astronomical Society, has chosen as his subject "The High Temperature Stars" The lecture will be delivered on May 9, and will contain some hitherto unpublished material on these important bodies

River Flow Records in the Ness Basin, Scotland

TO those interested for scientific and technical reasons in the availability of trustworthy data respecting river flow in Scotland, the appearance of two unostentatious pamphlets,[1] or monographs, containing records during recent periods of the Rivers Garry and Moriston, both in the Ness Basin, Inverness shire, will be welcome not merely for the records themselves and the information they afford at the moment, but also as indicating the inauguration of a series of observations which, if continued and extended over a period of years, cannot fail to be of considerable value when the time arrives for dealing with questions of river development

Capt W N McClean, at his own pains and expense, in conjunction with some voluntary helpers, has set on foot the systematic collection of hydrological data which no public or authoritative body in Scotland (or indeed in Great Britain) is empowered or disposed to undertake It is true that the Scottish Meteorological Department in Edinburgh has shown itself helpful in certain directions, and that it receives rainfall returns and provides general supervision over their collection, but the brunt of river gauging work falls at present on the private investigator "River Flow Records", the organisation of Capt McClean and his fellow-workers, is therefore an undertaking in the public interest which is deserving of acknowledgment for its altruistic labours The quarterly reports, which are on sale at a nominal figure, are distributed not only to all who have given facilities for, or assistance in, the taking of measurements, but also "to others who it is hoped will help in assuring continuous measurements of the water resources of the country"

The two rivers which form the subject of the monographs have equivalent catchment areas, but some appreciable variation in rainfall The River Moriston has a catchment area above the gauging section of 149 square miles, and the River Garry an area of 148 square miles. For both rivers, therefore, a flow of 400 cusecs is equal to 0 1 inch per day on the catchment area The flow off of the Garry, however, is considerably greater than that of Moriston on account of the larger area under heavy rainfall at the headwaters of the former For the two months of August and September in the period under review the ratio was as much as 3 to 2

The comparison of flow off and rainfall for the Moriston covers a period of a little more than nine weeks in the autumn of 1929 (July 27–Sept 30) based on actual measurements of flow made between Sept 13 and Sept 26 These few measurements, Capt McClean considers, are sufficient to enable a fair estimate to be made of the flow near Invermoriston from a moderately low river to a considerable flood, and permit of a rough prediction of flow for any recorded river height In default of more extended observations, the figures in the tables undoubtedly will be helpful, but it is obvious that there is need to supplement and compare them with later readings over a longer period, in order to increase the range, to eliminate errors, and to secure closer approximations

In the case of the Garry, measurements of flow were made between Aug 27 and Sept 11, 1929 Here, too, the records are for a very short period, but the author points to the observations which he kept of water level and rainfall during the three years 1913–15, the results of which were published in the *Proceedings of the Institution of Water Engineers* for 1927 The present records, therefore, are a resumption of the work previously carried on and unfortunately interrupted It is of interest to note that the flow of the Garry does not change with the rapidity of that of the Moriston on account of the long narrow exit from Loch Garry The loch rises gradually and has risen as much as 20 feet, storing at that level the equivalent of 3 inches of rainfall over its feeding area As a consequence, floods below the loch are delayed and spread over a long period

It is understood that not only are the present records to be continued, but also that similar readings and measurements are contemplated for other streams in the Ness Basin, including the Rivers Oich and Ness

BRYSSON CUNNINGHAM

University and Educational Intelligence.

BIRMINGHAM.—The Huxley Lecture is to be delivered on Mar. 6 by Sir William B. Hardy, Director of Food Investigation, Department of Scientific and Industrial Research, who has chosen as his subject "The Physical Basis of Life."

OXFORD.—For some time past questions of library accommodation and administration have been keenly discussed in Oxford. Some of the difficulties of the situation have been met by placing certain of the special book collections, for example, the Radcliffe Scientific Library, under the jurisdiction of the Bodleian. But it is felt that a complete reorganisation of the whole library system, including structural enlargement, arrangements for accessibility, facilities for readers and workers, the acquisition and proper housing of books, is urgently required. For this reason the generous offer of the Rockefeller Foundation to defray the expenses of a commission to visit modern university libraries and to report on their organisation, planning, equipment, and administration is especially to be welcomed. The commission, after finishing its inquiry, will be in a position to advise the University as to the best methods of bringing its library provision into agreement with modern requirements.

The annual report of the Visitors of the University Observatory has just been published. It contains a record of much work on the zones of the Astrographic catalogue and on seismological results up to 1926, including Prof. H. H. Turner's analysis of the earthquakes in the Philippines. A list is given of important papers by Prof. Turner and members of his staff that have appeared since the last report.

THE Borough Polytechnic, in Borough Road, London, was honoured on Feb. 20 by a visit from the Duke of York, on the occasion of the opening of its new buildings; this being the culmination of a series of similar functions which began with the opening last October by the Queen of the extension of the Regent Street Polytechnic. The Borough Polytechnic, the oldest and still the largest of the group of institutions founded under the scheme drawn up forty years ago by the South London Polytechnic Council, was opened by Lord Rosebery in September 1892. During the last seven years the volume of its work has increased by fifty per cent, and additional accommodation, for which the London County Council gave grants amounting to £80,000, had become urgently necessary. Even now, pressure on the available accommodation is excessive. The class entries total nearly 10,000, as follows: day schools, 568; day classes, etc., 287; evening departments of mechanical engineering and building, 1918; electrical engineering, 2068; chemistry, 667; chemistry of oils, colours, and varnishes, 401; mathematics, 893; tailoring, 126; bakery and confectionery, 308; art classes, 469; women's trade classes, 303; women's domestic economy classes, 664; language classes, 295; music and elocution, 374; gymnasia, 495. To the question "What can science do for industry?" many and various answers have in the course of the past few weeks been broadcast. The Duke of York dwelt, in his address, on a branch of science the votaries of which can indeed, albeit indirectly, through wise direction of consumption and beneficial influence on the moral and physical welfare of the personnel of industry, give more potent help than any other—domestic science with its correlative crafts. He commended the care taken by the Polytechnic in instructing girls and young women in the sciences and arts that make for the building up of good and comfortable homes.

Historic Natural Events

Mar. 3-4, 1886. Hurricane in Fiji.—This very severe hurricane caused the loss of many lives and the destruction of much valuable property, and was the worst experienced for many years. It travelled from north east, across the centre of the group, recurving over the Koro Sea and passing away to the south east, at an average speed of nearly 15 miles per hour. It had a calm centre with a diameter of 25 or 26 miles, in which the barometer fell to about 935 mb. (27.6 inches). Near the vortex the barometric gradient was 33 mb. (nearly one inch) in 50 miles. The town of Vuna in Taviuni was completely wrecked; nearly all the houses were blown down, and then were swept away by a hurricane wave or buried in the sand and shingle. From the coast to the tops of the hills nothing remained but bare sticks and the blackened, torn, and twisted relics of the foliage. Most of the small islands suffered from the storm wave, which came in like a wall, and penetrated inland as much as 700 yards. In some places debris was left in the trees 30 feet above high water mark. At Vanuaso a shark was killed among the houses.

Mar. 5-7, 1595. Great Floods.—The winter of 1594–95 was very severe; all the rivers of western and central Europe were frozen hard, including the Po and the lagoons of Venice. There was a great accumulation of snow, which began to melt rapidly at the end of February during a period of thaw; this and the break up of the ice caused great ice floods in the valleys of the Rhine, Moselle, and Elbe, which broke down the strongest stone bridges. The Thames was frozen, but there is no record of flooding in London.

Mar. 6, 1716. Remarkable Aurora.—A detailed account of this wonderful aurora was drawn up by Halley at the request of the Royal Society, and is published in *Phil. Trans.*, 1716, p. 406, under the title, "An Account of the late surprising Appearance of the Lights seen in the Air, on the sixth of March last; with an Attempt to explain the Principal Phænomena." This aurora was seen from almost the whole of northern Europe and so far south as the north west coast of Spain. In England the display commenced at 7 P.M. and lasted until 3 A.M. on the following morning when the moon rose. The most spectacular phase was from 7 P.M. until about 9 P.M., including the short lived appearance near the zenith of a 'corona' tinged yellow, red, and a dusky green. Throughout, the display was remarkable for the variety and rapidity of its changes as well as for its brilliance. Halley remarks: "Nor is the like recorded in the English Annals since the year of our Lord 1574"; also "... it seems, in little more than eighteen months, this sort of light has been seen in the sky, no less than five times; in the years 1707 and 1708." *Phil. Trans.*, 1716, p. 430, gives an account of the recurrence of the aurora on Mar. 31, April 1 and 2, 1716, *i.e.* about one solar rotation later. Wolf found that during the period 1716–19 sunspots were unusually numerous, though no large spot appears to have been observed about the time of this aurora.

Mar. 7, 1925. Abnormal Rains in Peru.—The coastal regions of Peru are in general almost rainless; for example, at Trujillo in the seven years 1918–24 inclusive, the total rainfall was only 1.4 inches. On Mar. 7-9, 1925, however, no less than 8.9 inches fell, and by the end of the month the total had risen to 15½ inches. Similar abnormal rains occurred all along the coast, beginning in January but reaching their maximum in March. Great floods resulted, doing serious damage to buildings, machinery, roads, and crops. The normal absence of rain is associated with the presence off the coast of the cold Humboldt

current, but at rare intervals a warm current, known as El Niño (The Child), because it usually appears about Christmas, flows down the Peruvian coast Early in 1925 this warm current was abnormally developed, temperature rose 10° or 20° higher than usual, and violent thunderstorms occurred

Mar 7, 1927 Earthquake in Tango District (Japan) —A strong earthquake occurred in the Tango peninsula on the north side of the main island of Japan The number of lives lost was 3017, while several small towns were ruined Crust displacements took place along two old faults nearly at right angles to one another On the Go mura fault, the ground shifted, along 11 miles, by so much as 9 ft 2 in horizontally and 2 ft 7 in vertically Repeated surveys in the central tract showed that movements continued for a year or more, and that the crust was divided into a number of blocks that moved easily and not always in the same directions

Mar 8, 1920 Haloes in America —A very fine display of solar haloes began at 11 30 A M at Ellendale, South Dakota, and other parts of the central United States In addition to the haloes of 22° and 46°, there were visible circumscribed arcs, parhelia, anthelion of 180°, and other phenomena, some of which exhibited brilliant prismatic colours The phenomena awakened great interest in the subject in America

Mar 8 (or 10), 1543 Mississippi Flood —The history of De Soto's expedition on the North American continent states "Then God, our Lord, hindered the work with a mighty flood of the great river, which at that time began to come down with an enormous increase of water, which in the beginning overflowed the wide level ground between the river and the cliffs, then little by little it rose to the top of the cliffs Soon it began to flow over the fields in an immense flood, and as the land was level without any hills, there was nothing to stop the inundation On Mar 18, 1543, when the Spaniards were marching in procession, the river entered with ferocity through the gates of the town of Aminoya (a short distance below the mouth of the Arkansas River), and two days later they were unable to go through the streets except in canoes The flood was 40 days in reaching its greatest height, which was April 20, and it was a beautiful thing to look upon the sea where there had been fields, for on each side of the river the water extended over twenty leagues of land, and all of this area was navigated by canoes, and nothing was seen but the tops of the tallest trees"

Societies and Academies.

LONDON

Royal Society, Feb 20 —**A C Davies, F Horton, and E Blundell** Critical potentials for the excitation of soft X-rays from iron Critical potentials for excitation of soft X rays from solids, and for production of secondary electrons from solids, under electronic bombardment, do not conform with the view that characteristic displacements take place of electrons forming the outermost extranuclear groups in the bombarded atoms The experiments deal with critical potentials for soft X ray excitation from iron, rolled into thin strip from a drawn wire, for different temperatures and also for the same specimen at room temperatures, after being subjected to various heat treatments Many critical potentials were produced, mostly persisting throughout the subsequent conditions of the target, once they had made their appearance, only one—at 201 volts—justifies the conclusion that its presence was dependent upon the iron strip being at a high temperature —**L M T. Gray and D W G Style** The absorption of light by chlorine, bromine, and their gaseous mixtures The independence of the absorption of chlorine of the intensity or nature of the incident radiation was tested by various methods Extinction coefficients of bromine vapour have been determined at room temperature for certain mercury arc lines The absorptions of mixtures of chlorine and bromine confirmed the existence of BrCl

Linnean Society, Jan 23 —**H W. Renkema and John Ardagh** Aylmer Bourke Lambert and his 'Description of the Genus *Pinus*' Lambert was the son of a country gentleman, of Boyton, Wiltshire Among his friends at Oxford, where he matriculated in 1779, were Joseph Banks and the principal founder, in 1788, of the Linnean Society, James Edward Smith Lambert was an original fellow of the Society and for fifty years was vice-president His chief contributions to botanical science were the accumulation of a large library and herbarium, and the spacious monograph of the genus *Pinus* A detailed description was given of the contents of all the copies of the volumes of the various editions to which the authors, in Holland and London respectively, have had access or on which they have been able to obtain reliable information —**G Tandy** Sundry observations on *Caulerpa* On the low wooded islands and inner reefs of the Australian Great Barrier system, two species are of importance as sand and shingle-binders, and it is probable that nowhere else in the world are conditions so favourable for this habit They are in the broad sense (for they are polymorphic) *C racemosa* (Forsk) J C Agardh and *C cupressoides* (Vahl) C A Agardh The latter is common on Batt Reef, which belongs to an inner series and is not a linear or true barrier reef The former is very common on Low Isles and is a member of the turf of the mangrove park.

Physical Society, Jan 24 —**J M Nuttall and E J Williams** A method of examining stereoscopic photographs The photographic plates are replaced in the cameras and illuminated, and a system of movable pin points is used to trace out the contour of the image (see NATURE, May 25, 1929, p 799) The chief advantage of the method is its simplicity—practically no computation is required and it is not necessary to know the stereoscopic angle, the magnification, etc —**Miss A W Leyshon** Characteristics of discharge tubes under 'flashing' conditions, as determined by the use of a cathode ray oscillograph Current voltage characteristics are determined Current time and voltage time curves are derived from the oscillograph records The method might prove useful in investigations on intermittent discharges in various gases under different conditions of pressure and disposition of the electrodes

Royal Meteorological Society, Feb 19 —**G C. Simpson** The distribution of terrestrial radiation (*a*) The geographical distribution of incoming and outgoing radiation during January and July has been determined and was exhibited on maps (*b*) The incoming and outgoing radiations for each 10° zone of latitude have been calculated for each month of the year (*c*) The result indicates great uniformity in the intensity of the outgoing terrestrial radiation, both in time and space, and that, except for small uncertain irregularities, the total outgoing radiation from the earth as a whole just balances the incoming solar radiation at all periods of the year —**C K M Douglas** The cyclonic depressions of Nov 16 and 23, 1928 Autographic records are reproduced showing the conditions close to the

centres of these two intense cyclones In both cases the first cold front soon advanced beyond the trough line of the cyclone This happens with nearly all intense cyclones, owing to the fact that the gradient wind behind the cold front is much greater than the rate of travel of the cyclone itself, even when this is large The speed of advance of these cyclones was greater than that of the general current in which they travelled This 'excess velocity' is characteristic of systems with warm sectors

DUBLIN

Royal Irish Academy (at Belfast), Feb 10—**K G Emeléus** Velocities of ions in the cathode dark space Existing data for the distribution of velocities in positive rays are discussed with the view of obtaining the distribution at the front surface of the cathode, little definite information is obtained, but an analogy is found between the capture of electrons by protons and by α particles The distribution at the cathode is calculated from Aston's and Brown and Thomson's results for the space charge in the dark space The possible effect of the cathode glow in distributing the velocities of particles traversing it is discussed, with the bearing of the results on sputtering—**A Mahr** The Viking sword from Ballinderry, Co Westmeath The blade shows the inlaid name of the maker, Ulfberht, a well known Frankish smith whose blades have been found scattered from France to Esthonia Another name, Hiltipreht, appears on the silver gilted quillon The name is Bavarian or Austrian, and Hiltipreht must have worked somewhere on the Low Rhine, where the Norsemen got their first supply of such weapons Hiltipreht was not the owner but the cutler of the sword In 841 the Vikings destroyed the famous town Wijck bij Duurstede in South Holland, at the time the important emporium for Scandinavian trade Our sword was presumably then brought to Norway and from Norway to Ireland Thorgestr, first Norwegian King of Dublin, raided Clonmacnois in 843, and as the Ballinderry Crannog is only a few miles distant we may assume that the sword came into Irish hands on this occasion—**J K Charlesworth** Some geological observations on the origin of the Irish fauna and flora During the glacial period, life was impossible in Ireland and off the western coast and just possible in the case of Arctic forms off the southern coast A fauna and flora entered over a land connexion during the Aurignacean oscillation, but with the exception of the Arctic species was probably exterminated during the succeeding glaciation The greater part of the Irish fauna and flora entered post glacially by a land bridge, aided by accidental dispersal

PARIS

Academy of Sciences, Jan 20—**Charles Moureu, Charles Dufraisse, and Pierre Lotte** The phenomena of luminescence in the satellites of rubrene Two phosphorescent hydrocarbons the so called 'brown' substance and the yellow substance—**Jean Baptiste Senderens and Jean Aboulenc** The catalytic de hydration of the fatty alcohols by alkaline bisulphates The boiling points of the first members of the series up to isobutyl alcohol are too low for any reaction with sodium bisulphate to take place, but from isoamyl alcohol onwards mixtures of ether and hydrocarbon are obtained Normal heptyl alcohol gives heptyl ether without heptylene—**Marcel Delépine** was elected a member in the Section of Chemistry, in the place of the late Charles Moureu—**L Godeaux** The connected points of cyclic involutions belonging to an algebraic surface—**P Vincensini** Certain normal congruences—**Bertrand Gambier** Systems of circles, of spheres, and of hyperspheres—**Pierre Humbert** Bessel functions of the third order—**K Kunugui** The classes of dimensions—**J A Grégoire** A new mode of transmission of rotations with conservation of the velocity between two shafts with variable angle Hooke's joint, a combination of two Cardan's joints, although theoretically perfect, gives rise to practical difficulties The new joint proposed is theoretically homokinetic, and has been practically realised in connexion with motor cars—**Renaux** Contribution to the study of the reduction of photographic negatives Discussion of a method of studying the position of stars from photographs—**J Dufay** A new astronomical photometer application to the study of two variable stars with eclipses—**J Galibourg** The ageing of cold hardened metals A continuation of the study of the effects of cold hardening on nickel—**P Vaillant** The absorption of cobalt salts in concentrated solutions From the whole of the experimental results obtained, it is concluded that for solutions of cobalt salts the modifications arising in the absorption spectrum from the substitution of one anion for another, from a change of concentration, or from a change of solvent, can be reduced to a Kundt displacement and a change of intensity These results are not necessarily in disagreement with the ionic theory—**P Dutoit and Chr Zbinden** The spectrographic analysis of organs The ashes of about fifty human organs have been submitted to spectrographic analysis by the arc spectrum method a summary of the results is given—**Edlén and Ericson** The spectrum of aluminium in the extreme ultra violet—**E Sevin** The means of deciding between the corpuscular nature and the purely undulatory nature of light and of the X rays—**Fahir Emir** Surface solutions on mercury Study of oleic acid A description of the special precautions taken to prevent oxidation of the mercury surface The thickness of the saturated film found was 24 A, as against 23 A found previously for water This confirms the hypothesis of molecular juxtaposition at the point of saturation—**Victor Henri** The heat of dissociation of the molecule of oxygen and the energy of activation of the oxygen atom From work based on the study of the absorption spectrum of nitrogen peroxide, the energy of the normal dissociation of the oxygen molecule is deduced as 128,000 calories—**Mlle Suzanne Veil** A mixed nickel cobalt oxide and the corresponding ferrite—**L Meunier and M Lesbre** A new method of observation of the evolution of solutions of chromic salts—**R Bernard and P Job** The oxidation of cobalt salts in alkaline media From a spectrophotometric study of this reaction, it appears that the passage from the cobaltous to the cobaltic state is through the intermediary of a percobaltic compound, CoO_2, in which the cobalt is tetravalent—**J Grard** Bromomalonic dialdehyde This exists in the forms CHO CHBr CHO and CH(OH) CBr CHO, the second of these possesses acid properties and gives well crystallised metallic salts—**L Palfray and B Rothstein** The 1, 3 cyclohexanediol (resorcite) stereochemical isomers and halogen derivatives—**F François** The selenoxanthydrols Their basicity The replacement of the oxygen of xanthydrol by selenium does not change the basic character of this alcohol—**H Besairie and Mlle E Basse** New stratigraphical and palæontological observations on the lower and middle Cretaceous of the province of Maintirano (west of Madagascar)—**Raymond Furon** Some new points of the geology of the western Sudan (Diawara, Kaarta, and Fouladougou)—**Laurent Rigotard** The rôle of sulphur in the formation of plant soil A study of the part played by sulphur in the formation of Alpine soils—**Louis Dangeard**: The presence of *Solenopora* in the oolitic and pisolitic formations of

the Lusitanian of Mortagne (Orne) —**M. Bridel and C. Charaux** Researches on the variation of the coloration of plants in the course of drying A new chromogen, oroberol, extracted from *Orobus tuberosus* —**B Soyer** The variation of the permeability of the cells in the course of growth in a ligneous plant Measurements of the permeability of the plant cell show that the migrations in spring and autumn are accompanied by marked modifications in the cellular permeability, modifications facilitating the circulation of the liquids in the tissues —**P Chevey** The value of the method of examination of the scales applied to fishes of the intertropical zone A difference of only 4° 5° C between the summer and winter temperatures of the sea is sufficient to change the rate of growth of fishes as shown on the scales Conclusions are drawn regarding the thermal changes in the coastal waters of Siam, Cochin China, and Tonkin —**J Millot** Colulus and non functional fibre producing structures in the Araneideæ —**C N Dawydoff** Some observations on the *Ctenoplana* of Chinese seas —**L Garrelon, D Santenoise, H Verdier, and M Vidacovitch** The pancreas and pneumogastric excitability The pancreas exerts an important action on the functional activity of the growing nervous system, by secreting and pouring into the blood a vagotonising hormone not identical with insulin —**René Hazard and Michel Polonovski** The physiological rôle of the tertiary amine function in the pyrrolidine piperidine nucleus The importance of the idea of isomerism —**R Meesemaecker** A new colour reaction of ergosterol The differentiation of ergosterol from irradiated ergosterol The colour is developed by addition of anhydrous zinc chloride, with or without acetic anhydride, to the ergosterol in chloroform solution With zinc chloride alone, the colour depends on whether the sample has been exposed to light or not —**L Lutz** The soluble ferments secreted by the Hymenomycetes Hydrocarbons and terpene oxides, constituents of the essential oils and the antioxygen function —**M Azéma and H Pied** Vanadium in the blood of Ascidians The presence of vanadium in the blood of *Phallusia mamillata*, first discovered by Henze, is confirmed, and two other Ascidians, *Ascidia mentula* and *Phallusia fumigata*, also gave strong spectroscopic evidence of the presence of vanadium *Botrylloides* and *B smaragdus* also contained vanadium, but in smaller amount —**Constantino Gorini** Heterogeneous mammary cocci, their dissociation —**E Piantureux** The nature of the transmissible lysis of bacteria —**Arnault Tzanck and Jean Charrier** The treatment of grave hæmorrhage of different forms

Brussels

Royal Academy of Belgium, July 6 —**Cl Servais** The geometry of the tetrahedron (3) The congruence of the axes of symmetry of the paraboloids conjugated to a tetrahedron —**Th de Donder** Affinity (2) Study of physico chemical systems with the added condition that the masses may vary —**Th de Donder** The invariantive theory of the calculus of variations (6) —**André Jamotte** Note on the discovery of a *Glossopteris* flora in the Lukuga valley, in the neighbourhood of Greinerville (Belgian Congo) The flora described shows great affinities with that of the middle part of the Ecca series of the typical region of the Karroo The Ecca series is considered to be of Permian age —**Erwin Schuntner** The application of continuous groups to discontinuous linear groups —**Constant Lurquin** The criteria of probability in the sense of Bienaymé Tchebycheff

Aug 3 —**Raymond Defay** Introduction to the thermodynamics of open systems —**Erwin Schuntner** The application of continuous groups to discontinuous linear groups (2) —**Lucien Godeaux** Remarks on the envelope of the Lie quadrics of a surface —**P E Bourgeois and J F Cox** Contribution to the research on the cause of the non-uniform distribution of the longitudes of the peristars of the spectroscopic double stars

Rome

Royal National Academy of the Lincei Communications received during the vacation, 1929 —**O M Corbino** Functioning of the triode with strong magnetic coupling with an iron nucleus between plate circuit and grid circuit —**A Angeli and Zvi Jolles** Certain oxidation processes determined by normal diazo hydrates It was shown recently that, under the action of stannous hydroxide, normal diazobenzene hydrate loses its oxygen atom to give rise to a highly labile product, C_6H_5 N NH, which afterwards under goes a series of transformations, one of these resulting in the formation of benzene This oxidising action of diazobenzene hydrate has now been demonstrated with ferrous hydroxide, hydrogen peroxide, hydroxylamine, potassium ferrocyanide, and ammonium sulphide —**B Longo and C Paderi** The biological significance of alkaloids on plants Experiment shows that alkaloids act, both on seeds and on plants containing them, as true excitants The exciting action is specific in the case of plants, but not with seeds —**B de Finetti** The possibility of exceptional values for a law of aleatory increments —**G Colonnetti** Alterations in the elastic condition of a mortised arch effected by addition of a chain —**B Finzi** Observations on the regular motion of viscous liquids —**F Lamberti** The component elementary motions of the relative baricentric motion of a material system —**E Raimondi** Dynamic effect of a translatory current investing a thin cylinder in the neighbourhood of an independent plane wall —**M Merola** Study of the variable SX Herculis A series of 82 photometric observations made on this star at Capodimonte between Aug 27, 1927, and Dec 1, 1928, allow of the determination of two maxima and two minima, thus confirming the irregularity of the period and of the light curve noticed by other observers —**S Aurino** The photometric system of Naples Comparison of the Draper Catalogue with the Astrographic Catalogue of Catania reveals the existence of a systematic error in the Draper Catalogue function of stellar magnitude The photometric system of Naples appears to be in excellent agreement with Miss Leavitt's system of photographic photometry (Harvard) —**C Cannata** The ballistic hypothesis and the verification of the law of areas in the orbits of telescopic stars Results are given which show that, for the orbits of telescopic stars, the perturbations induced by the ballistic hypothesis are generally insignificant Moreover, with rare double stars in which such perturbations appear relatively conspicuous, these are always within the limits of observational errors For orbits of slight eccentricity, the perturbations leave undisturbed the obedience to Kepler's second law —**E Persico and F Scandone** The Hall effect with extended electrodes (2) —**M Lelli** W Thomson's minimum heat theorem Comparison is made between the Joule heat evolved in unit time by a conductor traversed by a current and that evolved when, not the current intensity, but the values of the potential (supposed everywhere continuous) at the electrodes are fixed, and when also at every point Ohm's law of movement but not that of continuity of current is satisfied This is equivalent to comparing the effective stationary regime naturally established in the conductor with others provoked by keeping the terminal potentials unchanged by immission in certain zones and emission in others The result shows that, in the former case, the Joule heat generated is at a minimum, an extension

of Thomson's minimum heat theorem being thus deduced The corresponding theorem of electrostatics is capable of analogous extension —F de Carli Viscosity isotherms of binary mixtures (5) The system nitrobenzene stannic bromide Thermal analysis of this system does not reveal the formation of a compound between the components, but investigation of the viscosity-composition relationship demonstrates the existence of an additive compound, probably $2C_6H_5 NO_2, SnBr_4$, stable in the liquid state —Giambattista Dal Piaz Geological data on the regions of the Aurine Alps and of the Giant Vedrettes (Upper Adige) (2) —G Brunelli The skeleton of teleostians studied by means of radiography, in relation to the mechanics of movement —U Cassinis and L Bracaloni Normal and alimentary alcoholhæmia during physical exercise (2)

Diary of Societies

FRIDAY FEBRUARY 28

ELECTRICAL ASSOCIATION FOR WOMEN (at 46 Kensington Court), at 3 — L I Robinson Tariffs

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —C H N Lock The Equations of Motion of a Viscous Fluid in Tensor Notation —W L Watton A New Type of Dewar Flask for Use as a Calorimeter —R O Cherry Field Intensity Measurements around some Australian Broadcasting Stations

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) at 5 30

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —J Rowcroft The Design of Dynamos for Automobiles

ROYAL SOCIETY OF MEDICINE (Epidemiology Section) at 8 —Sir Leonard Rogers Further Experience in Forecasting Epidemics in India and their Bearing on the Reduction of Cholera Epidemics

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof G I Taylor A Tour in the East Indies

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales—Swansea—Sub-Centre).—I C Grant The Breaking Performance of High Power Switch gear and of a New Form of Quenched Arc Switch

SATURDAY MARCH 1

GEOLOGISTS ASSOCIATION (at Museum of Practical Geology Jermyn Street) at 2 30 —C P Chatwin Demonstration of The Palæontology of the Reigate Sheet

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —W Rothenstein Nineteenth Century Painting in France and England (2)

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College) at 5 —Prof W M Roberts Energy and some Points in Statics

GILBERT WHITE FELLOWSHIP (at Queen Square, W C 1), at 8 —Conversazione and Exhibition

MONDAY, MARCH 3

ROYAL SOCIETY, EDINBURGH at 4 30 —W N McClean River Flows of the Ness Basin —Gertrude Lilian Elles and C E Tilley Metamorphism in Relation to Structure in the Scottish Highlands

VICTORIA INSTITUTE (at Central Buildings Westminster), at 4.30 —Lieut Col T C Skinner The Significance of the Old Testament Scriptures to our Lord Jesus Christ.

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —C E Shattock Demonstration of Affections of Lymphatic Glands

SOCIETY OF ENGINEERS (at Geological Society), at 6 —J Pickin Machine Tools followed by a Film entitled A British Key Industry

ROYAL INSTITUTION OF GREAT BRITAIN at 6 —General Meeting

INSTITUTION OF AUTOMOBILE ENGINEERS (Bristol Centre) (at Merchant Venturers Technical College, Bristol), at 7 —H R Ricardo Combustion in Diesel Engines

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting) at 7 —J J Fisher and others Discussion on Push Button Control

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University) at 7 —Lt Col S E Monkhouse and I C Grant The Heating of Buildings Electrically by means of Thermal Storage

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section—London) (Annual Meeting) at 7 —Informal Discussion on Workshop Practice at Home and Abroad

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —F Pick The Design of Modern Railway Stations in Europe and America

ROYAL SOCIETY OF ARTS, at 8 —A B Searle Recent Improvements in Methods of Brickmaking (Cantor Lectures) (3)

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8 —Dr C Ainsworth Mitchell Circumstantial Evidence from Fibres and Hairs —H M Langton The Splitting of Castor Oil

TWICKENHAM LITERARY AND SCIENTIFIC SOCIETY (at Free Library, Twickenham), at 8 —Rev Dr J J Doyle Some Aspects of Higher Education in the United States

INSTITUTION OF THE RUBBER INDUSTRY (London and District Section) (at Engineers Club Coventry Street) —Dr H A Daynes Methods and Appliances used for the Control of some Manufacturing Processes in the Rubber Industry

TUESDAY, MARCH 4

ROYAL SOCIETY OF ARTS (Indian Section), at 4 30 —T M Ainscough British Trade with India

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 —Dr J A Glover The Incidence of Rheumatic Diseases (Milroy Lectures) (1).

Royal Institution of Great Britain, at 5 15 —Sir William Bragg X ray Determination of the Structure of Cellulose and Similar Substances (4).
Zoological Society of London, at 5.30.—A. B Martynov On the Trichopterous Fauna of China and Eastern Tibet.—Dr R. E. Drake Brockman A Review of the Antelopes of the Genera *Madoqua* and *Rhynchotragus* —M Burton Norwegian Sponges from the Norman Collection.—Dr Marie V Lebour The Larval Stages of *Caridion* (Crustacea) with a Description of a New Species —H W Kew On the Spermatophores of the Pseudoscorpions *Chthonius* and *Obisium* —W S Bristowe A Supplementary Note on the Mating Habits of Spiders
Institution of Electrical Engineers (North Western Centre) (at Engineers Club, Manchester), at 7 —E H Smythe and E G Weeks Low Temperature Carbonisation of Fuel, with Special Reference to its Combination with the Production of Electricity
Royal Photographic Society of Great Britain, at 7 —R. N Speaight Some Interesting Personalities in Photography
Institution of Automobile Engineers (at Royal Society of Arts), at 7 45 —H R Ricardo Combustion in Diesel Engines
Royal Society of Medicine (Orthopædics Section), at 8 30 —S A S. Malkin and others Discussion on Spasmodic Flat Foot.
Institution of Electrical Engineers (East Midland Sub Centre) —J J Denton Television—Progress and Applications

WEDNESDAY, March 5

Institution of Electrical Engineers (Wireless Section), at 6 —H J Lucas Some Developments of the Piezo Electric Crystal as a Frequency Standard —J E P Vigoureux The Valve Maintained Quartz Oscillator
Institution of Heating and Ventilating Engineers (at 29 Hart Street, W C 1) at 7 —Discussion on The Space Required for Central Station Equipment
Institution of Electrical Engineers (Tees side Sub Centre) (at Cleveland Technical Institute Middlesbrough), at 7 15 —B A Robinson Address.
Society of Public Analysts and other Analytical Chemists (at Chemical Society), at 8 —Dr S Judd Lewis (a) The Spectroscopic Investigation of Jams and the like (b) A Simple Polarimetric Test for Sugars in Jams (c) A New Kjeldahl Distillation Apparatus —Prof M S Eldin Bey The Detection and Identification of Alkaloids in the Saliva and Salivary Glands
Royal Society of Arts at 8 —Prof A R Ling Brewing as a Branch of Science
Institution of Chemical Engineers (at Geological Society), at 8.—Prof W E Gibbs The Formation and Growth of Crystals
Royal Society of Medicine (Surgery Section) at 8.30.—Pathological Evening
Royal Microscopical Society (Biological Section)

THURSDAY March 6

Royal Society at 4 30 —*Papers probably to be read* —W J Elford Structure in very Permeable Collodion Gel Films and its Significance in Filtration Problems.—T W Wormell Vertical Electric Currents below Thunderstorms and Showers —Dr N K Adam The Structure of Surface Films
Linnean Society of London, at 5 —Dr S. M Manton Notes on the Segmental Excretory Organs of Crustacea. V On the Maxillary Glands of the Syncarida —Prof G E Nicholls Addendum to his paper on *Micraspides.*—Major R W G Hingston In the Canopy of the Forest—British Guiana
Royal College of Physicians of London, at 5 —Dr J A Glover The Incidence of Rheumatic Diseases (Milroy Lectures) (2).
Royal Institution of Great Britain, at 5 15 —J B S Haldane Some Problems of Genetics
Royal Aeronautical Society (at Royal Society of Arts), at 6 30 —Major F M Green and H C H Townend Resistance of Air cooled Engines
Society of Chemical Industry (Birmingham and Midland Section) (at Birmingham University), at 6 30
Royal Photographic Society of Great Britain (Kinematograph Group —Annual General Meeting) at 7
Society of Chemical Industry (Bristol Section) (jointly with Institute of Fuel) (at Bristol University), at 7 30 —Dr F S. Sinnatt The Cleaning of Coal
Chemical Society, at 8 —G W Fenton and Prof C K Ingold Influence of Poles and Polar Linkings on the Course Pursued by Elimination Reactions Part VII A Generalised Form of the Olefinic Degradation of Sulphones —Prof C K Ingold and J A Jessop (a) Influence of Poles and Polar Linkings on the Course Pursued by Elimination Reactions. Part VIII. The Methylenic and Paraffinic Degradations of Sulphones (b) Part IX Isolation of Substance Believed to Contain a Semi polar Double Linking with Participating Carbon
Philological Society (at University College), at 8 —N B Jopson Work of the London Board of Comparative Philology

FRIDAY, March 7

Royal College of Surgeons of England, at 3 45 —T B Layton Demonstration of The Rhinological Anatomy of the Naso frontal Duct and the Hiatus Semilunaris
Royal Society of Arts (Indian Meeting) at 4 30
Royal Astronomical Society (Geophysical Discussion), at 4 30 —The History of Mountains Opener Dr Harold Jeffreys
Institution of Mechanical Engineers, at 6 —L W Schuster The Strength and Design of Fusion Welds for Unfired Pressure Vessels.
Society of Chemical Industry (Manchester Section) (at Engineers Club Manchester), at 7 —Dr F L Pyman Fine Chemicals
Institution of Electrical Engineers (Meter and Instrument Section), at 7 —A E Moore and W T Slater An Investigation of the Frequency Variations in Induction Watt-hour Meters
Royal Photographic Society of Great Britain (Pictorial Group—Annual General Meeting), at 7
North East Coast Institution of Engineers and Shipbuilders (informal Meeting) (at Bolbec Hall, Newcastle upon Tyne), at 7 15.—W D Horsley and others Discussion on The Effect of the Use of Electricity in Workshops on Efficiency and Costs.
Junior Institution of Engineers, at 7 30 —Lt. Col. G J Hartley Chile and Engineering in Chile
Institute of Metals (London Local Section) (at 83 Pall Mall), at 7 30 —A. Coad Pryor The Manufacture of Glass and some of its more Interesting Properties
Geologists Association (at University College), at 7 30 —Dr A. E Trueman The Lower Lias (Bucklandi Zone) of Nash Point Glamorgan —A A. Fitch The Geology of Etchingham and Robertsbridge, Sussex —G S Sweeting The Geological Structure of the Ashburnham, Battle and Crowhurst Districts, Sussex, with Notes on the Wealden Iron Ore
Royal Society of Medicine (Anæsthetics Section), at 8 30 —Dr C Donald Spinal Analgesia with Spinocain.—Dr H Jones Percain 'Ciba a New Regional and Spinal Analgesic with Special Reference to High Thoracic Nerve root (Splanchnic) Block
Royal Institution of Great Britain, at 9 —Dr C Tate Regan Angler Fishes
Society of Chemical Industry (Chemical Engineering Group) (jointly with Glasgow Section) (at Institution of Engineers and Shipbuilders Glasgow) —J S F Gard and R F Robinson The Insulation of Heated and Cooled Surfaces
Oxford University Junior Scientific Club —Prof C E Inglis The Construction of a Great Suspension Bridge

SATURDAY, March 8

Royal Institution of Great Britain at 3 —Sir Ernest Rutherford Atomic Nuclei and their Structure (1).

PUBLIC LECTURES

FRIDAY, February 28

Imperial College of Science and Technology (Department of Mathematics), at 5 30 —Prof C Størmer The Mathematical Theory of the Polar Aurora (Succeeding Lectures on Mar 5 and 7)
University College, at 5 30 —Prof E Gilson L Idée de Dieu dans la Philosophie de Descartes (Succeeding Lecture on Mar 3)

SATURDAY, March 1

Horniman Museum (Forest Hill), at 3 30 —Dr W G Ivens The Solomon Islands and their People

MONDAY, March 3

Medical Society of London, at 5 15 —Mrs Stella Churchill Infant Welfare Schemes (Chadwick Lecture)
Birkbeck College, at 5 30 —Prof Beresford Pite An Isometric Diagram of the Construction of the Dome of St. Paul s Cathedral Drawn by R B Brook Greaves

TUESDAY, March 4

University College, at 5 30 —Prof J de Vries Early Teutonic Civilisation (Succeeding Lectures on Mar 7 and 11)
Birkbeck College Chemical Society at 6 —Prof A McKenzie The Migration of Hydrocarbon Radicles in Optically Active Compounds

WEDNESDAY, March 5

King's College, at 5 30 —Prof P N Milyukof The Past and Present in Russian History
London School of Economics at 6 —Dr G H Miles The Problem of Incentives in Industry (Succeeding Lectures on Mar 12 and 19)
Belfast Museum at 8 —W R. Gordon The Progress of Modern Painting

THURSDAY, March 6

University College, at 5 15 —Prof O Meyerhof Chemistry of Muscle in relation to Problems of Cellular Physiology (Succeeding Lectures on Mar 7 10 and 12)
Imperial College of Science and Technology at 5 30 —Dr W F Bewley Diseases of Glasshouse Plants (Succeeding Lectures on Mar 13 and 20)
University of Birmingham —Sir William B Hardy The Physical Basis of Life (Huxley Lecture).

SATURDAY, March 8

Horniman Museum (Forest Hill), at 3 30 —Prof J R Ainsworth Davis Casting Life in New Moulds

CONFERENCE.

February 28 and March 1

Association of Technical Institutions (at Skinners Hall, Dowgate Hill, E C 4).
Friday February 28, at 10 30 A M —Lord Eustace Percy Presidential Address
C R Keene The Relationship between the Teaching of Art and Technology
Friday February 28 (*afternoon*), and *Saturday, March* 1 (*morning*).—F W Goodenough The Teaching of Salesmanship in Technical Colleges
G H Gater A Descriptive Account of Technical Education in London
E. Salter Davies, Sir Percy Jackson, and Principal J H Everett The Raising of the School Leaving Age and its Effect upon Technical Education
Principal R S. Clay and others Discussion on Technical Education for the Plumbing Trade, with Special Reference to the Rural Apprentice.

SATURDAY, MARCH 8, 1930

CONTENTS.

School Science and Educational Values.

WHETHER one agrees with Prof H E Armstrong or not—and frequently one does not—there is always to be found in his utterances much that is arresting, and in his writings much that stimulates One is often grateful to him for saying things which one is glad should be said—by someone else Even when his characteristic, pyrotechnic methods of expression become familiar, one is forced into the position of an attentive, if critical, student of his views One can enjoy his serious humour, admire his courage, deplore his exaggeration, but one seldom fails to experience the fresh air of common sense and the provocation to renewed thought about fundamental things which he offers to his audience When, in particular, he expresses an opinion on the teaching of science in our schools and universities, it is possible—rather it is profitable—to follow with care his exposition without necessarily finding oneself in complete agreement either with his generalisations or with his proposed remedies This attitude is presumably exactly that which our critic would wish to produce, for the policy of follow my leader is above all distasteful to him, and he would have both teachers and taught think and work out their scientific salvation each for himself

In a recent address to the West Kent Scientific Society, as reported in the *Kentish Mercury*, Prof Armstrong offered a vehement criticism of the type of education provided in both schools and colleges, his title was "Our Present Curse of Education", and his war cry "Down with the outside examiner" Teachers who are wise enough to read his address must expect to receive a 'wigging', and their anticipations will be duly realised They will, nevertheless, be indebted to him for his persistence in stepping on the weak planks in the educational platform, and might even forgive him his failure to commend the general stability of the structure which they have laboured, not unintelligently or unsuccessfully, to erect It is safe to say that Prof Armstrong is not alone in being dissatisfied with methods or with results, the urge to progress is a fairly common experience in educational circles It is equally safe to assert that our *Weltanschauung* has changed more rapidly than our educational technique But when Prof Armstrong asks us to agree that our schools remain happy hunting-grounds for pottering pedagogues, or that the admirable qualities of which the world is in need are the very opposite of those which characterise teachers as a class, or that no subject

is or can be properly taught in girls' schools, he will not be surprised to detect a suspicion of hesitation about our applause Nevertheless, if it is necessary to throw a few bricks in order to concentrate attention on the fact that we are not yet a scientifically equipped nation, that our only chance of happy survival is to make ourselves such, and that our leaders into the future must be scientifically minded men and women, then bricks let there be, and Prof Armstrong throws as devastatingly as any

Scientific or not, however, a nation may reasonably be expected to express itself adequately in its native language, and widespread inability to do so is specially to be deplored among its rising scientific generation English, he says, should be taught at all times and through all subjects of instruction, we can but agree Such incompetence is within the everyday experience of those who have to read science students' essays, and is still frequently noticeable in the reports of original work written by experienced investigators Latin, adds Prof Armstrong, is the only subject that is and can be properly taught to day—apparently because our schools are practically all 'in Latin hands', there are no skilled teachers for the other subjects, and foreign languages, in particular, are not regarded seriously Languages and mathematics, as he truly says, may be taught as definite subjects, the objective is clear, whilst in other class subjects there is no fixed method of approach

It is not entirely obvious whether it is for this reason, or in spite of it, that Prof Armstrong urges that more time should be devoted to the subject of languages, in his conclusion, however, he is probably correct Intercourse between the nations of the world is in a stage to warrant the extension, and mutual goodwill and understanding, whether scientific, commercial, or political, cannot fail to profit thereby Moreover, the taste for languages is a good and useful taste, and good taste should be acquired in early life He would next study geography, not geography as we ourselves were taught, but a living geography including geology, agriculture, etymology, and anthropology When we add the necessary basis of physics and chemistry, not forgetting also biology, we have the group of concrete sciences which, called geography or any thing else, is bound to figure in any intelligent story of man and his home Greater informality in school science there probably should be, but it will become doubly necessary to guard against permitting the book of knowledge to degenerate into a mere album of entertaining snippets Even more probably there should be some broadening of the scientific basis of instruction, particularly in the direction of simple biology This extension here and broadening there will, however, fail in its immediate purpose if it has in view merely an ideal universal code of education, it should be conceived as part of an elastic system adaptable to varying intellectual and material requirements Neither pupils nor teachers are cast alike in the same mould, so that we need not expect, however emphatic or unorthodox our views, to discover a universal solvent for such problems

Wholesale condemnation falls not only on school science as taught to day, but also on external examiners and all their works "If", says Prof Armstrong, "the external examiner is allowed to pursue his fell and cursed commercial purpose much longer, schools throughout the country will be ruined, they will lose all liberty to experiment, all liberty of teaching, and will turn out only automata" It can scarcely be supposed that Prof Armstrong, a scientific man, is attempting to deny the appropriateness of an independent test in helping to determine how a pupil is reacting towards his educational environment, so that it would appear that this is only his playful way of recommending modification in the nature of the tests to be applied, and in the circumstances of their application

In any event, the vocational significance of such educational tests is a matter to be reckoned with nowadays, when most men's brains have to earn their bread, and acceptable tests of some kind of commercial significance there will have to be It is not evident whether the stimulus of independent tests in promoting application to study is equally denied, or whether one is in future to rely on a universal consuming desire to acquire more knowledge and to acquire it in a logical way, on an irresistible impulse in youth to discover and apply scientific method The heuristic procedure is admittedly a potentially effective instrument in the skilled teacher's hands, and given a suitable medium it is no doubt capable of highly successful application The inquisitiveness of the scholar, constantly directed in logical channels by a sympathetic and provocative teacher, can be turned to good account in setting in motion the wheels of the mind, but even a well oiled engine requires fuel, as an agile mind requires a generous knowledge of fact That is not to say that fact is more important than method, it is to say that instruction has its proper and fundamental place in education Early specialisation is, of course, to be avoided, and a pass degree may have merits

unshared with an honours degree where the dis semination of knowledge rather than its acquisition is in question Specialists are frequently heard to complain of the narrow outlook which the present stage of development of science has forced them to maintain in the pursuit of their objective Is not therefore the danger in loosening external control of progress accentuated rather than reduced ? It might reasonably be argued that the heuristic method of all methods requires the watchful eye of an outside examiner, albeit a wise and sym pathetic one It is the very narrowness of school science of which Prof Armstrong complains

It is, indeed, even an open question whether research, by members of the teaching staffs of our universities, is not being exalted above its proper place in the scheme of things , whether the student is not being subordinated to the published paper , whether the teaching function, with its concomit ant requirement of leisure for thought and reading, should not receive greater attention and recognition This is a matter which has recently been discussed by the president of the Association of University Teachers, who views the present tendency with some concern The question, however, bears only in directly on our subject , another consideration has a more direct influence It appears impossible under existing conditions to remove Prof Arm strong's engaging and important problem from the domain of theory to that of practice, for the essence of the method is greater informality, elasticity, and individuality than is usually possible in a school or graduate college class of the usual size and hetero geneity Large classes, or even classes less large, are scarcely amenable to real heuristics, and failing the substance the shadow is probably of negligible value in comparison with the conventional article

Britain's Coal Resources

PROF J H JONES gives a very complete and useful summary of the existing conditions of the coal industry of Great Britain in a paper entitled "The Present Position of the British Coal Trade" in the *Journal of the Royal Statistical Society*, Vol 93, Part 1, 1930 He has collected valuable statistics from British and foreign sources and has published these in some twenty nine tables by way of an appendix to his paper , these figures form also the basis of the paper

Prof Jones has dealt with these statistics in the effective manner that might be expected from so accomplished a statistician Any defects in his treatment of the subject are due to the fact that he is a statistician and not a miner, and, therefore, overlooks some of the points which to a mining engineer would have been comparatively obvious Thus he deals in considerable detail with the falling off in British output, which he determines by a comparison of the present condition with conditions in 1913, the last pre War year He apparently overlooks the fact that 1913 was an exceptionally prosperous year for the coal trade, and should not be used as a basis for comparison

In any case, however, the fact that the British coal trade has fallen off compared to what it was in the years immediately preceding the War cannot be disputed Prof Jones does not, however, ap pear to see, as a mining engineer would, that this falling off is an inevitable consequence of the lead which Britain enjoyed for so long among coal producing nations He has overlooked the fact that coal, like every other mineral deposit, is a wasting asset, and that the nation which, like Britain, first developed and worked its richest seams, thus supplying the markets of the world, must inevitably sooner or later come to the stage when, with incipient exhaustion of these exception ally fine and accessible seams, other nations are able to enter into competition with it on more equal terms

The conclusion that Prof Jones reaches is as follows "The machinery which is now being established serves merely to relieve the pressure of excessive competition The cause can only be removed by a reduction in the producing capacity of the industry to the volume of demand which is likely to exist under the new conditions, I believe that we may reasonably expect the industry not only to recover some of its lost markets on the Continent, but also to benefit from a growing demand for home consumption"

As a statistician, Prof Jones is perhaps justified in his conclusion from a study of the statistics of the industry, but it is scarcely one that can be justified in the eyes of those who know all the circumstances of the case

Even a statistician might, however, find grounds for apprehension, seeing that Britain's probable coal resources are only about 3 per cent of the probable resources of the world, whilst Britain's coal output, as Prof Jones shows, is approximately one fifth of that of the whole world and fifty years ago was practically forty four per cent These figures surely indicate that Great Britain could not possibly maintain its leading position at the above rate of output for more than a limited period

Organic Chemistry in Peril

The *Times* of Feb 21 contains a remarkable article by Prof George Forbes, in which he describes his experience in 1877 when endeavouring to act as war correspondent in the Russo-Turkish war He was foiled by the Russian officials in every attempt that he made to join their army, until he met with a Prince Swiatipolk Mirski—a distinguished supporter of literature and the arts, well known in Parisian society—who was in charge of Transcaucasia After they had talked together for some time, the Prince suddenly asked him "Are you any relation of the late Principal James David Forbes?" When Forbes replied that he was his son, the Prince grasped him by the hand—'was very pleased to meet him', he had so much admired his father's discoveries in relation to glaciers and other branches of science—and roared with laughter as he remarked "And to think that they looked upon you as a Turkish spy" (I wonder if the prince did begin his sentence with that conjunction?) From that moment Forbes's difficulties disappeared he soon received a permit and was free to go under fire, he did so right valiantly "Thus, as constantly in my life," writes Forbes, "I was given the chance to do greater things than my own merit deserved, through the esteem, veneration and affection in which that great man, my father, was held" A more moving expression of filial reverence, of justified ancestor worship, has not been penned

All this by way of showing that it pays to have a father and have him remembered In London, we are in danger of forgetting our fathers, especially the fathers of organic chemistry and of disregarding their work—of showing ourselves unable to appreciate its value and the supreme importance of carrying it on, with ever increasing intensity of effort Two most weighty letters were printed in Nature of Feb 15 from Sir William Pope of Cambridge and Prof Jocelyn Thorpe of the Royal College of Science, London, both protesting against the proposed substitution of physical chemistry for organic chemistry, when Prof Robinson leaves University College, London, to succeed the late Prof W H Perkin, jun, at Oxford I agree with every word they say To adopt the policy that is advocated will not be merely suicidal but criminal, at a time when the two great organic chemical industries of dyestuffs and pharmaceuticals are beginning at last to flourish here It involves going back upon every argument we have used, during and since the War, in support of the promotion of chemistry as the backbone of manufacturing industry Take the extreme case of the production of ammonia from atmospheric nitrogen—this is sometimes spoken of as if it were an achievement of physical chemists in fact, it is almost entirely a capitalistic and engineering triumph, there is very little chemistry in it that is in any way special Whatever it be, it is useless as a practical enterprise without organic chemistry Anyone, given the capital, can now make ammonia the difficulty is to sell it with advantage The whole commercial future of nitrogenous fertilisers is a problem of the very highest organic chemistry—of agricultural and physiological chemistry As a matter of fact, the nitrogen industry, at present, is working in physical chemical blinkers, it has put itself far too much under the guidance of men without vision

We need to go back to the 'forties to read what was said by the late Lord Playfair—one of the very few broad minded scientific men who have advised Great Britain, one of the chief founders of our system of scientific technical education In the Hofmann Memorial Lecture (Chemical Society, 1893), he tells how the illustrious Liebig, in 1841, published his celebrated work—"Chemistry of Agriculture and Physiology"—and of its magic effect Personally conducted by Playfair, he toured England in 1842, with the immediate effect of making chemistry a popular science The School of Mines was opened in Jermyn Street, University and King's Colleges began to give attention to laboratory teaching, then in 1845 came the Royal College of Chemistry, with Hofmann at its head, next to Liebig the greatest organic chemist—taking the times into consideration—the world has known

Such is the debt of chemistry to agriculture—it were time that it returned the compliment and gave competent chemists to agriculture—competent organic chemists but also sons of the soil, with full understanding of living things Even physical chemistry to day, great as has been its vogue, is neither physics nor chemistry, its business is but to point the bricks of the great structure laid by the chemist's trowel, chiefly the organic chemist's We have not a competent agricultural chemist to day (there has not been one since Liebig), we have not a competent physiological chemist, that is to say, one sufficiently gifted with the divine afflatus of chemical science and also a 'physiologist' To arrive at full understanding of the right ways of feeding the soil, the plant, the animal—ourselves included—we must be chemists, especially on the organic side

I have long foreseen the danger In an article which I wrote for the *Manchester Guardian* (special Levinstein number), during the War, I contended that, if Manchester wished to give chemistry a recognised position consonant with its industrial importance, a special chair should be endowed in the University to which a stipend of at least £5000 should be attached It mattered not whether anyone were worth so much at the moment demand would create supply Chemistry is dead in Manchester to day and not fully alive elsewhere—yet Manchester is the metropolis of the great organic textile industry Only one organic chemist of high degree is left to us now that we have lost Perkin Something we must do, to counter the selfish action of industry—this, too, in the ultimate interest of industry We hear of commercial magnates with salaries up to £30,000 No commercial magnate can have the same ultimate value as a real organic chemist

Claiming, as I can, Hofmann as my spiritual father, I am able to look back sixty five years across the field of chemistry and, in some measure, evaluate the progress made in its several sections Progress there has been—great general progress—but the mathematical physical section has been too much pampered It has even brought the wrong type of mind—the accountants'—unduly to the fore Chemistry, after all, is a science of deeds, things have to be made, not merely talked about hypothetically and weakly measured—it is largely an affair of fingers and an art The organic chemist, in particular, is highly imaginative but his imagination rests upon an entirely sane background X rays are but serving to justify his highest flights of imagination—going no further

We are not really getting down to the big problems We have to view with concern the slowness with which our attack upon the carbohydrates matures Little more is *settled* of the nature of starch than was established by O'Sullivan and Horace Brown in my early days We have not yet *decided* even the con texture of the glucoses Beilstein, the record of organic chemistry, already has 12 large ordinary and 3 supplementary volumes and will not be completed in less than ten more It already costs £60 Only real men can teach a subject of such magnitude

To serve the ends of the British Empire, we have to strain every nerve to secure more competent chemists of all kinds—no delay is permissible At the moment, industry here and, particularly, in America is thwarting academic efforts to produce them, by tempting men of potential ability prematurely into industry, before their intelligence is sufficiently ripened by confining their labours, it is tending to promote intellectual sterility, parents so trained cannot have healthy offspring

University College, in virtue of its Medical School, is marked out as the great biological centre of the future That future will be indefinitely postponed, unless the College maintain a highly developed, complete Department of Organic Chemistry—pure and applied To think that a few calculating machines will suffice us in producing a great work of art is obviously absurd

Prof Forbes was helped by a single father I can claim the support of several—of an entire organic ancestry Hofmann put me to work under Frankland and Frankland sent me on to Kolbe three lineal descendants of Liebig Returning, I was adopted by Williamson of University College and became the first Perkin's colleague Being of such organic parent age, I may claim to speak with some authority I would urge that it is impossible to think of the service Williamson rendered to organic chemistry, by resolving the chaos surrounding alcohol and ether then, in the College where he taught, to do the great wrong to organic science that is now threatened It cannot be! It must not be!

HENRY E ARMSTRONG

The Scientific Principle of Uncertainty

'IF the actual history of science had been different, and if the scientific doctrines most familiar to us had been those which must be expressed in this [statisti cal] way, it is possible that we might have considered the existence of a certain kind of contingency as self evident truth, and treated the doctrine of philo sophical necessity as a mere sophism "

This is not a quotation from an exposition of the quantal doctrine of the essential uncertainty of physical knowledge, which recently startled the philo sophical world It is taken from the inaugural lecture at Cambridge in 1872 by Clerk Maxwell, the creator, in conjunction with Boltzmann, of the science of dynamical statistics, the development of which gave promise of rapid progress about that time

The essence of the matter is that in this subject, as it gradually emerged in close connexion with gas theory, the primary feature was the invariant specification of the differential receptacles or cells for the statistics, propounded as an analytical result by Liouville in his *Journal*, vol 3, pp 342 9 (1838), and rediscovered to some purpose by the redoubtable pair, Maxwell and Boltzmann, about 1876 They were stimulated to the broadening of the subject by introduction of general ised co ordinates in the modern manner, by the physical vitalising of the Hamiltonian revolution in dynamics of date 1834, by Thomson and Tait in their "Natural Philosophy" in 1868 This re statement in generalised form appears to have been first exhibited in H W Watson's tract on gas theory in 1876, written with access to Maxwell's private notes pub lished in his memoir of 1879, and its lucidity was re marked on by Boltzmann The essential point was that in the specification of these invariant cells, a range of any co ordinate δq occurred multiplied by a range of the cognate momentum δp, and that the factors of this product could not be separated, so that any refinement of exactness in one variable involved a loosening in the other

JOSEPH LARMOR

Cambridge, Feb 14

Unemployment and Hope

IT is certainly a hopeful sign to find in NATURE of Feb 15, p 225, the interesting article under this heading by Mr W G Linn Cass, ending with the plea that originality and freshness of view in this old question were never in the history of the world more or more urgently needed than now I trust it may not fall on deaf ears, for in my experience, hitherto, scientific men have shown themselves in this question perhaps rather more bigoted and intolerant than can be wholly accounted for by their natural conservatism Possibly it is a suppressed consciousness of guilt, for, after all, unemployment or leisure, two ways of stating essentially the same condition, is the most natural as it is the inevitable consequence of their achieve ments

In any conceivable economic system, labour saving is the unquestioned goal of the application of science to industry, but few dare to see the process through to its absurd end under the present system As science multiplies by n the productability of labour, $(n-1)/n$ lose their livelihood and with it their title to consume, so that, but for the 'dole' and similar confiscatory legislation, consumption would be re duced to $1/n$ No more stupid or criminal waste of creative effort surely could be imagined

It may be comforting, but it is certainly very short sighted to argue that it will all come right of itself in the end, because scientific invention and discovery create more work than they displace Admittedly, at first the $(n-1)$ surplus goes to feed the $(n-1)$ dis placed men who are put to create new productive enterprises When these, in turn, produce, the original deadlock returns in exaggerated form In this respect New Testament economics was clearer than that taught in modern universities, since it distinguished the cate gory of the wealth which perishes from its negative form, debt, which accumulates at interest Unem ployment, or leisure, should be the avowed object, as it is the inevitable consequence of scientific produc tion

I cannot subscribe so heartily to the Biblical economics, which I suspect has influenced Mr Cass to invert the natural function of industry, and to put production as second to the exercise of faculty and the growth of character The right use of leisure is—Who can doubt it?—one of the dominant prob lems of a scientific civilisation But why should industry be necessarily charged with this alien func tion? It is educational, and should be the care of universities, training schools, theatres, the churches, the Press, and so on The end is surely easier of attainment by leisured people, supported by what science is capable of supplying without taking their entire lives for it, than as a means of livelihood in competition with scientific methods Much as on lookers may deplore the mechanicalisation of industry,

Mr Ford is probably accurate as to the present psychology of the worker in his belief that what they want is to be told what to do, how to do it, and be allowed home in the quickest possible time They prefer, as most of us scientific workers would, leisure to task work, however interestingly it may be disguised

It is also hopeful to note the growth, if slow, of the conclusion reached by all who have recognised that the problem is not one of production but of distribution, that no reform is possible without reform of the money system Mr Cass refers very cautiously to "financial reform in the direction of a measurable amount of inflation, possibly on the lines suggested by Arthur Kitson, Douglas, and others", as a possible way of approach to the unemployment problem The present state of inflated France, reported to be able to find work for a million alien workers, and deflated England with between one and two million workers permanently unemployed, is eloquent of the importance to industry of the distributing mechanism, the money system Both rob Peter to pay Paul, the creditor class in the one case and the taxpayer in the other, bearing the loss

I differ from the reformers cited, while in general agreement with their diagnosis of the industrial and economic situation, in the belief that it is not only possible for a scientific era to devise a stable monetary unit of value, but that it is of far more consequence to its social well being, even than invariable standards of weights and measures To me, the present system, in which the quantity of money in circulation is a function of the extent people are allowed to overdraw their accounts and spend what no one knowingly has given up, is mere 'account cooking', already responsible for much if not most of the present deadlock To believe that greater laxity in accounting is going to produce anything but more confusion and bitterness is impossible What I think is needed is a much clearer perception of what each expansion of industry involves, the permanent locking up of some definite quantity of wealth in the enlarged flow—not the same wealth but the same quantity permanently—and the necessity of accounting for this quantity just as for capital expenditure in a straightforward manner, without as at present simply drawing upon the general purchasing power of money to meet the outlay Granted this, with the accountancy of the monetary system kept according to the ordinary laws of arithmetic, I do not see any difficulty in maintaining a monetary system with an invariable standard of value and yet capable of distributing all that society is willing and able to produce

FREDERICK SODDY

APPRECIATION by some of our leading men of science of the difficult problems raised by the increasing application of science to industry is to be welcomed, whether it be due to a less suppressed consciousness of guilt or to greater leisure, and the position calls not for less science but more, especially in the sociological sphere rather than in the physical Progress in the social sciences has probably not kept pace with that in the physical, so that there is some uncertainty and bewilderment as to the best and wisest organisation and utilisation of the marvellous wealth and resources placed at our disposal by chemistry, physics, and engineering A greater knowledge and more skilful use of the statistical method in economics and politics as exemplified in Sargant Florence's great work and others, together with more boldness in making social experiments, would greatly accelerate progress in the desired direction Definite measurement and experimentation, and ultimately we shall hope, prediction also, are probably much more possible in the social sciences than is commonly supposed, and can alone justify the appellation of 'scientific' They should replace the vague evolutionary fatalism, by which things will eventually right themselves, and the unsubstantiated hypotheses which still cloud our horizon

Prof Soddy suggests that in one important respect, which appears to be that of relative values, New Testament economics, or the ancient oriental theocracy, is clearer than that taught in modern universities, and if this be so, then one should be the more, rather than the less, disposed to subscribe to the Biblical economics which may have induced me to invert the natural function of industry, making production secondary, for here also we are dealing with the determination of relative values But perhaps this division of the aims of industry into moral or spiritual, on one hand, and material on the other, was not the best or most complete analysis that could be made, and was done chiefly with the view of emphasising one aspect of industrialism that might just possibly be overlooked

It is not easy to agree that unemployment and leisure are essentially two statements of the same condition except by violent distortion of definitions, or that industry should have no responsibility in connexion with the right use of leisure Of course, under modern conditions, industry is not actually "charged with this alien function", but industry certainly largely determines the amount of leisure, and its proper use is by no means a matter of indifference to the prudent and up to-date employer He does not think it advisable entirely to disclaim all responsibility herein, and rely wholly on the theatres, churches, and Press, or even on the universities and schools Even Mr Henry Ford, or perhaps he more than any one else, realises the importance of a right use of leisure, and in proportion as Mr Ford is correct in his view of the relations between man and his work, a rather hopeless view it seems, so much the more important is leisure and its use

W G LINN CASS

An Apparent Rôle for the Thymus (in Calcium Metabolism)

IT has already been reported (Harris and Moore, *Biochem Jour*, **23**, 261 1929) that hypervitaminosis D always involved an atrophy, indeed eventually virtual disappearance, of the thymus, and similar changes in other lymphadenoid tissue—a discovery which has since led us to the observation that an equally remarkable fall occurs in the lymphocyte count in the same circumstances, for example, down to a reduction of more than 90 per cent below the normal average range The atrophy of the thymus might perhaps have been accounted for simply as a feature of the general inanition a similar change is seen in vitamin B deficiency and sometimes in starvation yet this explanation seemed unsatisfactory Loss of weight, for example in vitamin A deficiency, does not always produce such an effect

In searching for a meaning for the atrophy of the thymus, and bearing in mind that the other manifestations of hypervitaminosis were the opposite to those of vitamin D deficiency, one could not overlook the suggestive fact that in clinical rickets the organ is indeed frequently hypertrophied Yet current physiological text books are unanimously in agreement with a recent monograph on the thymus (Hammett, Berlin, 1928) which asserts that "the function of the thymus

is unknown." Similarly it was authoritatively stated (Park, *Physiological Reviews*, 1923) that a belief that the thymus was concerned in calcium metabolism had "been challenged and overturned." However, on assembling the relative material one is confronted, once more, with a significant set of observations which, although mostly long since forgotten, and originally given a far different emphasis and interpretation, have for the most part been confirmed or extended.

(1) Atrophy of the thymus occurs in hypervitaminosis D (this is, *hyper*phosphatæmia, hypercalcæmia, hypercalcification, etc.) (Harris and Moore, 1929; Harris and Stewart, *Biochem. Jour.*, 23, 207; 1929.)

(2) Hypertrophy of thymus occurs, conversely, in rickets (that is, *hypo*phosphatæmia, etc.) (Marfan, 1922).

(3) Extirpation of thymus gives rise to rachitic lesions (Basch, 1906; Klose and Vogt, 1910; Matti, 1913), or to a typical osteomalacia (Scipaldes, 1919), or, in birds, to a deficiency of shell (or albumin) in the eggs (Riddle, 1924).

FIG. 1.—On right hypervitaminosed rat (after 8 days feeding on synthetic diet containing 0·1 per cent of irradiated ergosterol) showing disappearance of thymus. On left a normal control litter mate (fed on non irradiated ergosterol) to show the size of normal thymus (marked in solid outline in key diagram at side).

(4) Similarly atrophy of thymus, induced by thymotoxic serum, was accompanied by diminished density of and lowered CaO, MgO, P_2O_5 content of bone (Ogata, 1917).

(5) Conversely, grafting of thymus into a normal animal results in increased compactness of its bone (Demel, 1922).

(6) Feeding of thymus to salamanders in the larval stage (that is, when they have as yet no parathyroids) produced typical tetany, relieved by calcium administration (Uhlenhuth, 1918).

(7) The thymus partly involutes at adolescence.

With these observations before us, there seems no escape from adopting as a working hypothesis the view that the thymus is involved in calcium and phosphate (the two are interconnected) regulation. Thus, if one assumes, as a simplest form of this hypothesis, that the thymus is concerned in promoting calcification, one can explain very readily the facts summarised above. In rickets the organ would be hypertrophied as a result of 'overwork'; the reverse effect would naturally be seen in excessive vitamin D intake; excision of the thymus clearly would tend to prevent normal calcification, while thymus grafting or feeding would obviously have the reverse tendency; and, finally, there would certainly be a lessened need for such an organ once the laying down of the bony frame had been concluded, at adolescence.

As already indicated, several of the observations recorded above have been overlooked or disputed. In the latter connexion it is easy, however, to see why some difficulty was experienced in confirming any early work in relation to rickets; for at the time the various causative factors (Ca : P balance, vitamin deficiency) were far from being understood, so that even in control animals experimental rickets could not be satisfactorily produced. For example, it is sufficient to mention that the accepted disproof of any possible connexion between the thymus and calcium metabolism rested on evidence no more substantial than that of Renton and Robertson (1916). These workers dismissed the possibility of a relationship between rickets and the thymus on the grounds that they found it impossible to keep their normal control dogs any more free from rickets than they did their thymectomised dogs. With modern technique and knowledge different conclusions may be drawn.

The parathyroids, as is now well known, must be included among the factors concerned in calcium regulation. Admittedly, the mechanism of calcium metabolism as a whole is complex, and it is further certain that interrelations between the thymus, parathyroid, and other organs of internal secretion must become involved, quite apart again from separate questions of absorption in the gut under the control of vitamin D. The intricacies of the question cannot be gone into here, except to emphasise that it is desired to say nothing which might appear to exclude the other apparent activities of the thymus (in relation to the lymphocytes, or to the bone marrow, or nuclear metabolism), or, again, to draw a distinction between the thymus and other lymphoid tissue. But, in the almost unexampled chaos which prevails in the extensive literature describing the supposed functions of the thymus—'antitoxic', 'immunological', 'sexual', 'epithelial', and so forth—or its supposed irregularities, status lymphaticus and the like—a single working hypothesis which serves like the above to unify so many experimental observations deserves careful consideration.

The Quantum Theory of the Kinetics of Homogeneous and Heterogeneous Reactions

CLASSICAL physical chemistry cannot explain a whole number of questions connected with the kinetics of homogeneous and heterogeneous reactions. For the explanation in particular of unimolecular reactions the constant of velocity of which does not depend on pressure, it is necessary to postulate a more or less complex mechanism (Lindemann, Lewis and Perrin, etc.). A number of investigators (Oppenheimer, Bourgin) have recently pointed out that, from the point of view of quantum mechanics, spontaneous disintegration of molecules which had not received the activation energy required by the classical theory is possible. In the present communication we give some preliminary considerations resulting from a study of the problem of kinetics of reactions.[1]

If spontaneous disintegration of the molecule is possible, there must be supposed a mechanism analogous to the mechanism of emission of α particles by the nuclei of radioactive elements (Gamow), or ionisation of an atom by the outer electric field (Oppenheimer) or Auger effect. These phenomena may be schematised, as was done by Gamow in his case, making use of the idea of the transition of particles through the

potential jump Similarly, quantum mechanics describe the emission of electrons from metals effected by the electric field (a number of papers by Fowler and Nordheim, and others) In the case of spontaneous disintegration or rearrangement of the molecules, we may assume, for example, the scheme shown in Fig 1, of dependence of the potential energy on the distance between the parts of the molecule, where A is the activation energy of the molecule, W the

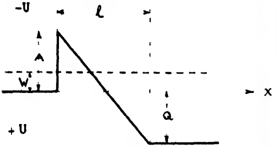

FIG 1

vibrational energy, Q the heat of reaction, and l the distance from the equilibrium position in which the molecule ceases to exist as a whole

Assuming for this scheme the probability of disintegration (or rearrangement) at $|A| > |W|$ to be approximately

$$D(W) = (4/|A|)(W)^{\frac{1}{2}}(|A| - W)^{\frac{1}{2}} \exp - \frac{4k(|A| - W)^{\frac{3}{2}}}{3a(Q - A)/l} \quad (1)$$

where

$k^2 = 8\pi^2 m/h^2$ (Fowler and Nordheim, $F = a(Q - A)/l$), taking $D(W) = D_1(W)$ at $|A| \leq |W|$ (Fowler and Nordheim, *Proc Roy Soc*, 119, 181, 1928) and using the formula

$\frac{M}{\sqrt{T}} e^{-W/kT}$ for the probability of the state with the energy W, we obtain for the constant of velocity of the reaction (v)

$$v = \frac{\beta M}{\sqrt{T}} \left[\int_0^A e^{-W/kT} D(W) dW + \int_A^\infty e^{-W/kT} D_1(W) dW \right] \quad (2)$$

where βM is the proportionality coefficient

The character of the function $v(T, Q, A, l)$ obtained by different methods is qualitatively confirmed by experimental data A similar formula (expressing the dependence on temperature) was obtained by Bourgin

The analysis of the assumptions on which the deduction of the formulæ is based, and their detailed comparison with experiment, will be given in a subsequent comprehensive paper For the present we may point out that the heat of activation A, contained in them, is not identical with the heat of activation determined experimentally from the temperature dependence of v

According to (2), v is independent of the concentration, which is in agreement with the well known properties of typical unimolecular reactions However, the influence of temperature on the vibration levels of the molecule is such that it renders possible the formation of Bodenstein's energetic chains, which cannot exist under very low pressures Only in the presence of chains can the almost complete cessation of the unimolecular reaction under very low pressures be accounted for (Sp[illegible]er)

The influence of the surface on the reaction cannot be reduced simply to a superposition of a field of double surface layer on the molecule The phenomena of catalysis require another treatment, but they also appear to be fully explained from the point of view of quantum mechanics We should consider disintegration of a molecule as a phenomenon analogous to spontaneous ionisation of an excited helium atom Both the component parts of the molecule should be considered like two electrons of helium This is connected with the probable emission of free atoms into the volume during absorption

It is also evident that, from this point of view, the unimolecularity of the majority of reactions, taking place in the superficial layer, can be easily explained (spontaneous disintegration becomes possible near the surface) as well as a series of other peculiarities of catalysis (the action of promotors, interface action, etc)

In a similar way there follows from it the increased probability of the disintegration of molecules when united into complete aggregates (or under increased pressure) The same circumstance provides a method of extension of quantum mechanics to reactions of a higher order Thermodynamic considerations lead to analogous conceptions, if we assume the equilibrium process to be unimolecular in one direction and a reaction of higher order in the other

L ROSENKEWITSCH
Physical Technical Röntgen Institute,
Leningrad, Dec 26, 1929

[1] After this communication had been posted there was pointed out to us the preliminary paper of Langer (*Phys Rev* 37 92 1929) devoted to the quantum mechanics of chemical reactions This communication (and especially our further investigations) seems to us to have an interest of its own, since we put the question (and solve it) in a way which differs in many respects from Langer's (*Added in proof*)

Galls

THE paradoxical interrelationship between the plant and the gall producer, the larva, led to a correspondence between Mivart, Romanes, and other biologists, which appeared in NATURE of 1889 and 1890, and has since been extensively reproduced in works on cecidology, such as Kuster's "Die Gallen der Pflanzen" (pp 365 372, 1911) I have attacked the problem from a purely chemical point of view, my results leading me to the conclusion that the interrelationship between the gall producing larva and the plant may be regarded as one of inter compensation

In 1786, Scheele recorded the observation that *freshly collected* galls produce gallic acid from gall infusions, and that old galls are not capable of inducing this reaction This was confirmed by Robiquet, senior (1836), and Robiquet, junior (1854), but was discredited by Van Tieghem (1868), who concluded that the previous workers had been dealing with material infected by *Aspergillus* and *Penicillium*, which fungi have since been shown by Fernbach and Potevin (1901) to contain the enzyme tannase, which hydrolyses gallotannin into gallic acid

The remarkable fact that Scheele and the two Robiquets were so definite in their assertion led me to repeat their experiments, with the result that I have confirmed Scheele's original observations The production of gallic acid by freshly collected galls obviously shows that plant galls contain tannase, at the same time suggesting that the tannase is present in the gall producing larvæ and not in the galls themselves To test this hypothesis, the larvæ of *Pontania proxima* × *Salix caprea*, were chosen, and, using the method elaborated by Nicholson and Rhind (1924), it was found that they contain comparatively large quantities of tannase, about eight times as much as is found in the same weight of *Aspergillus niger* The gall produced by this larva had the obvious

advantage of being free from inquilines, and the larva is known to deposit its waste products outside the gall.

The presence of tannase in the larvæ of the gall producer throws new light on the points raised in the above mentioned correspondence in NATURE. It has been shown by Kustenmacher (1895), Magnus (1914), and others, that the larva lives on the plant by the production of diastase and invertase. This is counteracted on the part of the plant by an increase of tannin (thus, the oak tree contains from 5 to 10 per cent tannin, whereas oak galls contain as much as 60 per cent), which is known to precipitate both these enzymes. The decisive action, however, remains to the larva, since tannase destroys gallotannin. The accumulation of gallic acid thus produced is also effectively disposed of by the larva, as previously shown by me (1919), when I found that dryophantin (the red colouring matter of the pea-gall) is a glucoside of purpurogallin, an oxidation product of gallic acid.

These observations, which may be represented as follows:

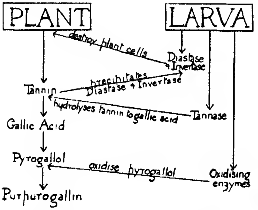

FIG 1

suggest that the interrelationship between the gall producer and the plant is therefore parasitic, the initial action of the larva being counteracted by tannin production on the part of the plant.

The Original Mode of Constructing a Voltaic Pile

A SHORT time ago I had occasion to turn up a number of papers in *Nicholson's Journal* on early electro-chemical research in England. I was puzzled to find there certain statements regarding Volta's pile which, at first sight, seemed directly at variance with modern views.

Nicholson and Carlisle, after constructing a pile "of seventeen half crowns with a like number of pieces of zinc and of pasteboard soaked in salt water", showed by the aid of Bennet's electrometer that the silver end of the pile "was in the minus and the zinc end in the plus state".

At first, I believed this to be a mistake in the text, but the same statement was found in the early papers of other workers, for example, William Cruickshank, Colonel Haldane, and Humphry Davy. Davy and Cruickshank each state that hydrogen and metals (or alkalis) are disengaged at the "zinc wire", that is, the wire connected to the zinc plate, and oxygen and acids at the "silver wire".

Being at a loss to account for these statements—all consistent but apparently contrary to fact—I made a silver-zinc pile, arranging twenty shillings and twenty discs of zinc in series as shown, each pair being separated by blotting paper (Fig. 1).

(This is the arrangement given in most text-books of physics and is analogous to Volta's arrangement of pairs of plates in his "couronne de tasses".)

The pile gave an appreciable current when soaked in brine and behaved quite normally, liberating iodine from potassium iodide at the end of a wire joined to the silver. The apparent inconsistency was explained by a further reference to Nicholson's paper. His description of the construction of the pile is as follows:

FIG 1

"Take any number of plates of copper, or which is better, of silver, and an equal number of tin, or which is better, of zinc, and a like number of discs or pieces of card or leather, or any porous substance capable of retaining moisture. Let these last be soaked in pure water, or which is better, salt water or alkaline lees. The silver or copper may be pieces of money. Build up a pile of these pieces; namely, a piece of silver, a piece of zinc, and a piece of wet card, and so forth in the same order till the whole number intended to be made use of is builded up" (page 179, *Nicholson's Journal*, July 1800).

The arrangement of the discs is as shown in Fig. 2. Apart from a negligible contact potential difference between the two end pairs of plates, the voltage of this pile will be the same as the one represented in Fig. 1. In other words, the extreme silver and zinc plates of the series A and B (Fig. 2) are practically useless and merely conduct the current to or from the next plates. The wire connected to the silver plate will thus have the same potential as the next zinc plate, which is negatively charged, while the 'zinc wire' will have the same potential as the next silver plate (positively charged). This construction was evidently the outcome of the theory of Volta, who regarded the points of contact of the pairs of plates as the main source of the electrical energy.

Colours of Inorganic Salts

PROF. SAHA's suggestion (NATURE of Feb. 1, p. 163) that colour in inorganic compounds depends upon the existence of an electronic state of the metal ion separated from the ground state by about 18,000 wave numbers finds some support at least from work which has been begun here upon the general problem

of crystal spectra There is a mass of evidence for his theory from the study of the rare earths (see particularly Freed and Speeding, *Phys Rev*, September 1929), but since the rare earths are exceptional because of the incompleteness of an inner quantum group with a consequent shielding of f electrons in it, it is more interesting to consider the spectra of chromium salts

The absorption spectrum of a crystal of anhydrous chromium chloride does not, of course show the sharp lines characteristic of rare earth salts As Stoner has shown, for any transition element where the incomplete quantum group is of highest total quantum number there is an interaction between the l moments of the ions in the lattice, that is, in the crystal of a chromium salt the outer electrons of each chromium ion exert an effect upon the outer electrons of the ions near to it in the lattice Actually, there are for $CrCl_3$ four or possibly more bands between 5700 and 7200 A, the bands, much broader than the lines of rare earth salts, are yet narrow compared with the shapeless bands common in crystals and solutions, and show the spectroscopic effect of the l interaction Besides these bands in the red, there appears to be a similar but weaker system in the blue-green Either of these systems is within the limits of Saha's prediction

Unpublished work on a number of crystals of hydrated and complex salts confirms the supposition that the fairly narrow bands in the red and blue are due to Cr^{+++} The bands are unaltered in frequency and seem usually to be sharper than in the anhydrous salt It may be that the sharpening is a real effect, due to the weakening of the l interaction by the presence of the co ordinated electrons from the H_2O groups, this would lead to $\sqrt{l(l+1)+4s(s+1)}$ rather than $\sqrt{4s(s+1)}$ for the magnetic moment (in Bohr magnetons) of such a co ordinated ion The magnetic evidence, which is scanty, is against this, and it may easily be that the sharpness is a matter of quality of the crystals examined

Besides the narrow bands, however, a broad structureless region of absorption from the green to the orange occurs in the spectra of all hydrated Cr^{+++} salts It seems to be caused by the co ordination electrons, and is similar in position to the only band given by the CrO_4 and Cr_2O_7 ions At low temperatures the Cr_2O_7 band has been resolved by Obreimov into a structure which is probably caused by Cr - O vibrations of different (n', n'') values, the effect of lowering the temperature is, first, the lessening of l interaction, and secondly, the simplification of the vibration possibilities of the ground state (The effect can be seen by considering the Boltzmann distribution over the intra-group (Cr - O) vibration, of the order of 500 wave numbers, and the lattice frequencies associated with it, of the order of 50 wave numbers)

It is expected that chromium salts will soon be examined at low temperatures, and it should not be difficult to decide upon the cause of the band introduced by the co ordination electrons The comparison between $CuSO_4 5H_2O$ and $CuSO_4$ is enough to show further that transitions of low energy content are made possible by the electrons of co ordinated groups, at the moment it is not certain whether the transitions are confined to the co ordinating electrons, or whether the co ordinating electrons merely have a disturbing effect upon the incomplete group of the ion concerned The answer, particularly for groups of different kinds co-ordinated in various numbers, will bring detail to our knowledge of co ordination

Until this is worked out, any account of colour in the compounds of transition elements is incomplete Of the two possible causes, the one defined by Saha is known and can usually be predicted, the other, which can happen through the formation of complex ions from atoms the incomplete quantum group of which is of highest total quantum number, is still unknown

Angular Leaf-Spot Disease of Cotton

Bacterium malvacearum, the causative agent of 'black arm', or angular leaf spot disease of the cotton plant, has been described in certain recent papers as capable of producing a systemic infection of the plant without, however, causing any manifest symptoms of disease until external conditions become suitable for the development of local lesions Further, it has been claimed that this infection may extend to the developing ovules, so that internally infected seed results, which on germination may give rise to infected plants, the degree of such infection being conditioned in large measure by the soil temperature prevailing at the time of germination

These hypotheses were of such importance that a grant was made by the Empire Marketing Board to the Rothamsted Experimental Station for the construction of apparatus in which soil and air conditions are independently controlled A number of experiments have been made on cotton plants growing in this apparatus, and certain conclusions relating to the above mentioned theories have been reached Cotton seed from the Sudan derived from heavily infected plants, and therefore on the above theory presumably internally infected, was grown at a range of soil temperature with all other environmental factors constant Seed which had been thoroughly disinfected externally produced seedlings showing no infection at any temperature Seed sown untreated resulted in seedlings with a small degree of infection, showing a maximum at a soil temperature of about 27° C Plants from seed which had been soaked in a strong suspension of the organism showed a considerably greater degree of infection, again with a maximum at 27° C, but with some disease even at 40° C (a temperature several degrees above the maximum at which the organism has been grown in pure culture) Finally, seed in which the organism had been artificially introduced within the seed coat produced seedlings nearly all of which were infected at all temperatures, even up to 40° C It will be seen that these results lend no support to the hypothesis of natural internal infection, but indicate that primary infection arises from the attack of bacteria present on the outside of the seed

In order to test the theory of latency of the parasite within the plant, these same seedlings which had shown primary infection were allowed to grow on under conditions suitable for the development of the disease, as shown by the fact that plants side by side with them which had been sprayed with a pure culture of the organism developed heavy infection In no case did the unsprayed plants show any further disease in the newly formed leaves and stems as would be expected if the theory of internal spread were correct A detailed account of these experiments will be published at an early date in the *Annals of Applied Biology*.

Returning to the hypothesis of internal infection of seed, attempts in the laboratory to isolate the organism from the tissues of the embryo have invariably failed Many different kinds of organisms, both fungi and bacteria, occur, however, between the

seed coat and the embryo, and on one occasion out of many trials *B malvacearum* was recovered from this position

A point of interest, and one which may prove to be of great importance in the life history of the disease, is that this bacterium has been found to show the phenomenon of 'dissociation' At least three 'dissociates' have been isolated, all of which are culturally, and to some extent morphologically, quite distinct, one being possibly identical with the so called 'common yellow saprophyte of cotton' These 'dissociates' arise in single cell cultures and appear to be produced in an obligate order, that is, 'A' produces 'B', 'B' produces 'C,' and so on, there being some suggestion that the cycle may be a closed one This phenomenon of dissociation appears to be correlated to some extent with the production of some of the newly observed growth forms recently described by me (*Proc Roy Soc*, B, **105**, 1929)

Glasses Transparent to Ultra-Violet Radiation

IN his letter to NATURE of Jan 18, Dr English suggests that our conclusion (NATURE, Sept 21, 1929) that "complete degeneration by a mercury arc lamp results in a greater loss of ultra violet transparency than does natural solarisation", is merely a confirmation of his statement (*Glass*, Sept 1928) that eight hours' exposure to a mercury vapour lamp is equivalent to six months' exposure to sunshine

So far from confirming his statement, we cannot even agree with it We have proved quite definitely that an exposure of two hours at a few inches from the mercury vapour lamp produces far more degeneration than would an eternity of sunshine

Dr English appears to ignore completely the most interesting phenomenon of the rejuvenation of ultra-violet glasses in sunshine *after* being degenerated by mercury vapour lamps Our letter was concerned almost entirely with this discovery, which to our minds proves conclusively that exposure to lamps emitting radiation of wave lengths shorter than that received from the sun can be no safe guide to the behaviour of glasses when exposed to sunshine We understand that this discovery of the phenomenon of rejuvenation of artificially irradiated glasses has already been confirmed by the Bureau of Standards

We are surprised that Dr English prefers to substantiate his arguments with photographs of spectra, surely a dangerous procedure—he himself condemns it (*Glass*, September 1928, pp 388, 389)—rather than to consider figures, accurately determined, showing the actual percentage transmission of specimens of identical thickness under different conditions We believe that all accepted authorities agree that the only trustworthy methods for the comparison of specimens of glass are those employing a photoelectric cell, vacuum thermopile, or similar quantitative instrument One such method was described briefly in our letter (NATURE, Sept 21, 1929)

We did not say in our letter that natural solarisation was complete in a few days Our figures show, however, that it can be practically so in four very bright days

New glass exposed in winter will, of course, age slowly compared with that exposed in summer

Monomolecular Films of Batyl Alcohol

SOME measurements which I have made on mono molecular films of batyl and chimyl alcohols (isolated from shark liver oils by Prof J C Drummond) throw some light on the molecular structure of these compounds They have been shown to be, respectively, an octadecyl glyceryl ether (Heilbron and Owens, *Jour Chem Soc*, 942, 1928) and a cetyl glyceryl ether (Drummond and Baker, *Biochem Jour*, **23**, 274, 1929), whether the hydrocarbon chain is attached to the glyceryl group at the α or β carbon atom has not hitherto been decided

My measurements give 26 sq A for the cross section of the head group of batyl alcohol This agrees with the value for the α monoglycerides (Adam, Berry, and Turner, *Proc Roy Soc*, A, **117**, **532**, 1928) If batyl alcohol had the symmetrical β structure, its mode of orientation would require a larger area than this, comparable with the 36 sq A found for mono octadecyl malonic acid (N K Adam, private communication)

In view of these facts, therefore, it seems highly probable that batyl and chimyl alcohols have the unsymmetrical α structure

Viruses and Life

MR GEOFFREY SAMUEL states in NATURE of Jan 11, p 51, that he has difficulty in distinguishing the suppositions vitamol and virus Virus connotes a something of unknown constitution that can pass through filters and that causes specific disease Vitamol is supposed to be of molecular structure with attributes of life, and might be parasitic or symbiotic or lead an independent existence In the study of the viruses the methods of the biologist seem to have reached their limit, and the concept and the word were offered in the hope of attracting the attention of physicists who might be able to cast a ray of light on the matter

If structure is for function and not function for structure, then function should precede For the development of structure that facilitates metabolism (say an envelope having certain qualities) there should be metabolism to facilitate

In the broad theory of evolution there is at present a hiatus between the non living and the living, a gap which the theory requires should be bridged

J J DAVIS

A Deep Sea Echinoid in British Waters

ON Feb 13 we took a single specimen of the Spatangoid *Urechinus naresianus* in a bucket sample at 110 metres, seven miles south of Sanda, off the Mull of Kintyre It was a young individual only, 5 mm long The general colour was whitish, and the tube feet yellow, two or three large pedicellariæ on the aboral side were tipped with deep red The sample was a coarse shell gravel with a fairly large mixture of sand

This is the first record of the species in British waters, and with the exception of a single record at 760 metres, referred to by Mortensen as untrustworthy, its previously known bathymetric range was c 1450 to 4480 metres

HILARY B MOORE

Marine Station,
Millport

Scientific Research and Modern Life

THE recently published report of the Department of Scientific and Industrial Research[1] covers the period Aug 1, 1928–July 31, 1929 It is signed by Lord Parmoor and includes the short report of the Committee of the Privy Council, and the longer report of the Advisory Council, together with summaries of the work done under the direction of the various research boards and by the research associations which have received grants from the Department, and also appendices dealing with finance, publications, and the organisation of industrial research in various parts of the British Empire

Originally appointed by an Order in Council of July 28, 1915, the Committee of the Privy Council, consisting of the holders for the time being of certain Ministerial offices, is charged with the duty of directing the application of the sums of money provided by Parliament for the organisation and development of scientific and industrial research The gross estimate for the present year is £644,379, of which £31,071 is for headquarters administration, £32,000 for grants, £512,570 for research work and research establishments, and £68,738 for the Geological Survey of Great Britain and the Museum of Practical Geology, the administrative control of which was transferred to the Department in 1919

Much detailed information is given regarding the allocation of the money, from which it is seen that the net cost of the National Physical Laboratory during 1928–29 was £89,861, of fuel research £77,877, of building research £32,362, of forest products research £34,327, and of food investigation £18,546 Of the various research associations, during eleven years the British Scientific Instrument Research Association has received £100,484, the Woollen, Cotton, Linen, and Rubber Research Associations in nine or ten years have received respectively £54,643, £92,662, £57,282, and £30,983, while altogether twenty three associations have received grants The total expenditure on the National Physical Laboratory was £195,164, but the receipts from outside bodies, firms and Government departments, amounted to £105,303

Though, considering the immense interests involved the sum at the service of the Department is comparatively small, it is probable that the influence of the work of the Department is felt in every part of the Empire, while perhaps no portion of the national income is expended with more beneficial results Agriculture, food, housing, heating, lighting, clothing, transport, and communications, all profit by the investigations either directly carried out by the research boards or assisted by the Department, and science is not only applied to difficult industrial problems, but it is also made to minister to our everyday needs in a thousand ways The storage of fruit, the production of beet, cutlery manufacture, laundry work, flax growing, boot-making, furniture, anthrax from skins and hides, coinage, the ageing of rubber, dentists' fillings, mites in flour, the cocoa moth, water purification, fish and salt meat, are all among the things which are being investigated and will undoubtedly pay for investigating No fewer than fifty boards and committees are shown as directing the inquiries, which affect the whole population On these committees sit some of the most distinguished men of science in Great Britain, and their services to the nation are none the less valuable because in many cases they are given voluntarily These committees may indeed be regarded as a great general staff organised for the application of science to our common wants

It is impossible in a short article to do justice to the great range of subjects that fall within the province of the Department, but to illustrate the close relationship of its work and everyday life we have selected the reports of the Fuel, Food, Building, and Forest Research Boards Second in importance to none is the national question of fuel, whether used for industrial or for domestic purposes Presided over by Sir Richard Threlfall, the Fuel Research Board has local committees in all the coal producing areas and maintains the Fuel Research Station at Greenwich Of this station the Advisory Committee remarks ' We take this opportunity of expressing to Your Lordships our appreciation of the value of the work of this Station Your Lordships can be confident that we now have a national organisation for fuel research which is not excelled in any other country "

When the Fuel Research Board started its work, it gave a large degree of priority to all problems of carbonisation, these being considered of importance from the point of view of smoke abatement and of the production of oil from home resources It was also desired to stimulate industrial development Then, too, the Board was asked to advise on the composition and quality of gas for public supply In connexion with these matters, problems in both high temperature and low temperature carbonisation have been attacked with noteworthy results Now it is proposed to carry out a general investigation of furnace design with particular reference to the burning of pulverised fuel, which is being introduced both ashore and afloat The chief technical problem here is to secure complete combustion in a small space, hitherto it has been considered necessary to have large combustion spaces, but for this there does not seem to be any basic necessity The production of metallurgical coke, the manufacture of water gas, the hydrogenation of coal, and the composition of tar are all being studied An outstanding feature of the year was the starting up of the low temperature carbonisation plant at the Richmond Gas Works, erected to the designs worked out at the Fuel Research Station After preliminary difficulties were overcome, the plant was successfully put into commission, and the new domestic fuel was placed on the market as 'Gloco'

The Food Investigation Board is presided over by Sir J G Broodbank, while Mr W C D Whetham

[1] Department of Scientific and Industrial Research Report for the year 1928–29 (Cmd 3471) Pp v+200 (London H M Stationery Office, 1930) 3s 6d net

is chairman of the management committee of the Low Temperature Station for Research in Biochemistry and Biophysics at Cambridge Our fuel supplies are ample, our food supplies come from all over the world, and the successful preservation and carriage of fruit, vegetables, meat, and fish affect every home The storage of fruit has been studied for ten years, and it is proposed to publish a comprehensive report on it Special attention has been given to apples, and recent investigations show that there is a critical low temperature for each variety of apple, below which the fruit rapidly deteriorates in storage For the study of fruit an experimental station is being erected at East Malling, and for the study of fish a research laboratory is being inaugurated at Aberdeen Towards the cost of these the Empire Marketing Board is assisting The value of the fish landed in Great Britain last year was £18,000,000, the value of the meat imported, £109,000,000—figures which indicate the importance of the trade in these commodities

While many of the inquiries led to long and difficult experiments in the laboratory, an example of work of more immediate practical application arose through requests made by the Sheffield and Leicester Corporations The question was whether the hanging of meat improved its palatability Experiments were made with meat conditioned at 32° F and 41° F up to ten days hanging, and it was found that the palatability was improved, the flavour was retained, and the texture and juiciness of the meat improved In the tests, assistance was received from members of King's College for Women and the staff of Messrs J Lyons and Co

Houses, furniture, and clothing are as necessary as food and fuel, and the work of the Building Research Board, the Forest Products Research Board, and that done by the Cotton, Woollen, Silk, Leather, Boot and Shoe, and other Research Associations, afford many examples of the value of the scientific method applied to age long problems Limes, plasters, cements, paints breeze, artificial stone, the weathering of stone, the vibration of buildings, wind pressure on structures, are being investigated by the Building Research Board, while the Forest Products Research Board is dealing with the anatomical structure of woods, the seasoning of furniture timbers, the shrinkage and deterioration of timbers, the testing of pit props, and the habits of the various insects which destroy our roofs and furniture Many firms apply to the Boards for information, and, in addition to advisory work at home, much has been undertaken for places so far apart as Burma, British Honduras, Australasia, and Kenya

In other directions work is proceeding on metals and alloys, boiler plates and ingot steel, corrosion, the fatigue of metals, electro deposition, springs, radio telegraphy and telephony, lubrication, cast iron, refractories, and many engineering problems While one department is engaged on the study of steel, another is considering the advisability of establishing a national locomotive experimental station, and yet another is doing work of value for our cathedrals and churches Canada, Australia, New Zealand, South Africa, and India are all following in the footsteps of the Mother Country they all have research organisations, and of their activities the report gives a brief review

A New High Voltage Research Laboratory

THE opening by Sir Ernest Rutherford of the high voltage research laboratory of Metropolitan Vickers Electrical Co, Ltd, at Trafford Park, Manchester, on Feb 28 is a noteworthy event The increasing use of the outdoor type of construction for high voltage apparatus makes it necessary to determine how this apparatus will act during gales, thunderstorms, and snow storms As the standard pressure for distributing electrical energy in Great Britain is 132,000 volts, and a factor of safety of three or four is desirable, it is very advisable that all devices for use in high voltage lines should be tested at pressures of several hundred thousand volts

In the present state of our knowledge, the performance of insulating material under very high pressures can in general only be determined by experiment Although there are now several laboratories abroad which have facilities for testing at a million volts with a large reserve of power, yet with the exception of the high voltage equipment at the National Physical Laboratory, Teddington, there was none in England It is highly satisfactory, therefore, that one of the largest industrial firms should have built a million volt laboratory under the supervision of its able engineers

The present laboratory consists of two semi independent main buildings and an annex The smaller of the two main buildings, which is 47 ft long by 67 ft broad, was built in 1923 as a 500,000 volt power frequency laboratory When it was decided to extend the equipment to give a million volts, the second main building, 67 ft by 86 ft, was laid down with a wall in common with the original building The latter is now equipped with devices for producing transient voltages and is called the 'surge' laboratory The annex contains the materials and physics laboratories and a machine room where all the generators and running machinery are isolated so as to reduce noise

The main electrical equipment consists of two 500,000 volt, 500 k v a, 50 cycle transformers, one being located in the main laboratory and the other in the surge laboratory For producing a million volts, the two transformers are connected in cascade by the well known Dessauer method The second transformer, the one in the main laboratory, is shown in Fig 1 As the primary winding of this transformer has a potential difference to earth of 500,000 volts, the whole transformer has to be thoroughly insulated from the earth This is done by means of pedestal pillars which support the tank

containing the transformer The two transformers are practically identical in construction, each being of the core type with each limb wound They are both immersed in oil

The accurate measurement of high voltages is a problem of considerable difficulty The standard method is to use two spherical electrodes, then, if their potentials are equal and opposite at the instant of the discharge, the potential difference between them can be computed with an accuracy of about one per cent, provided that there are no brush discharges taking place in the neighbourhood When one of the electrodes is earthed, the accuracy obtainable is not so high, possibly because the potential of the 'earthed' sphere is not zero

The method adopted in the new laboratory at Trafford Park depends on the theorem that the average charging current of a condenser is proportional to its capacity and to the *maximum value* of the voltage Hence when the capacity and frequency are known and the average current due to the voltage is measured, the maximum voltage can be deduced A meter is so arranged that its reading gives the voltage directly The condenser employed consists of large surfaces, each twenty feet in diameter and having air between them (see Fig 1) The surfaces employed are flattened and symmetrical about a vertical axis One is supported directly on the bushing insulator of the high voltage transformer, and the other is suspended immediately above it from the roof This condenser is the largest high voltage condenser yet constructed

The power rating of each of the transformers is 500 kilovolt amperes, so that very large currents can be supplied at the instant of spark-over In order to get satisfactory results, it is well known that it is necessary to have a large amount of reserve power available The control of the generators which are housed in the machine room is done from the control desks in the laboratories Push buttons control the starting and stopping of the driving motors, the rheostats which govern their speed and the frequency meters The potentiometer regulators which control the voltage are motor driven and give a uniform rate of voltage variation over the entire range with the motor running at constant speed

The photograph of a power frequency arc at a pressure of 970,000 volts is shown in Fig 2 The spark gap is 12 ft The man shown in the illustration was not present when the arc occurred, if he had been he probably would have been killed. He is merely included in the photograph to indicate the scale of the phenomenon, this was done by a double exposure On first entering the laboratory, one is impressed by the large amount of floor space which is apparently not utilised Remembering, however, that at a million volts 12-ft arcs can occur, it will be seen that any material or apparatus being tested must be at least that distance away from walls and objects connected with the earth Taking the dimensions of the transformer into account, it was found that a clear space at least 30 ft in diameter was absolutely necessary

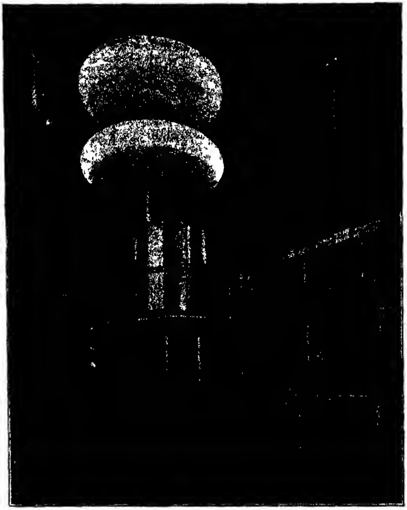

Fig 1 —Interior view of the main High Voltage Laboratory at Trafford Park

In order to make full scale tests of large porcelain insulators immersed in oil, it was found advisable to make a tank 25 feet in diameter and 10 feet in depth This has a volume of about 4000 cubic ft and would contain about 20,000 gallons of oil Good insulating oil is not cheap, so this must repre-

sent quite a large amount of capital The necessity also of keeping it dry and clean must add considerably to the cost It will be seen that these million voltage tests must be very expensive The majority of the tests will be carried out by the two transformers used individually at 500,000 volts or less In the materials laboratory there are three transformers producing voltages of 11,000, 22,000, and 100,000 for ordinary tests Two tanks are provided, for making tests in hot and cold oil There are four testing chambers in the middle of the room, where the materials can be tested at various temperatures and humidities

In the surge laboratory (Fig 3), apparatus is provided for testing devices and materials when subjected to transient voltages produced in various ways In systems used for transmitting electrical power, three kinds of surges are recognised first, those caused by a sudden variation of the load or the 'runaway' of a generator, secondly, those due to high frequency surges of internal origin caused by switching or by an arcing fault, and thirdly, the surges caused by atmospheric disturbances, including lightning discharges Modern operating experience in Great Britain where the neutral is earthed indicates that lightning is the only source of overvoltage that has to be guarded against The design of the insulators, therefore, must be such that the minimum amount of damage is done when the lightning arc over occurs The dangerous transients are the 'impulsive rushes' which were described fully and experimentally demonstrated by Sir Oliver Lodge so long ago as 1889 (*Jour Inst Elect Engin*, vol 18, p 386, 1889)

By arranging a condenser so that it is suddenly discharged when a spark gap flashes over, it is easy to get what Lodge called an impulsive rush By arranging a series of them in parallel, we can construct an impulse generator The generator in the surge laboratory can produce transient voltages up to 1,500,000 A mechanical rectifier is installed which produces a voltage of about 700,000 This is mainly used for operating the impulse generator Another set equipped with thermionic rectifiers is generally employed for direct current voltage tests Its maximum voltage is 250,000 volts, and its terminals can either be at equal and opposite voltages or one of them may be earthed

A special Schering bridge has been constructed for measuring dielectric losses at pressures up to 500,000 volts Electro mechanical tests on porcelain insulators, and design studies on switch gear and transformer parts, have frequently to be carried out in this laboratory It is one of the best equipped laboratories in the world, and Messrs Metropolitan Vickers Electrical Co, Ltd, are to be congratulated on having recognised always that it is necessary to use the best and most scientific methods of testing the materials they use in manufacturing their machines and devices and for determining their factors of safety

In declaring the laboratory open, Sir Ernest Rutherford expressed the hope that before long we may be able, by using millions of volts, to produce copious streams of high velocity atoms and electrons in the laboratory An abundant supply of swift particles would open up many new avenues of attack on the fundamental problems

FIG 2 —Power frequency arc at a pressure of 970 000 volts in a 12 ft. gap The man was photographed separately

of physics Unfortunately, the finances of the ordinary university laboratory are very limited It is too much for a university to hope for a laboratory like this one approaching a cathedral in size It is possible, however, that an apparatus may be devised which can be operated by a small

transformer in an ordinary-sized room giving ten million kilovolts to a vacuum tube Such a piece

FIG 3 —Impulse generator in Surge Laboratory

of apparatus would be a great help in physical research, and considering the great progress made by engineers in recent years, Sir Ernest believes that the design of such a device does not offer insuperable difficulties He congratulated the Metropolitan Vickers Electrical Co, Ltd, and its research department on its far sighted policy in initiating high voltage research

Obituary

MR A A CAMPBELL SWINTON, F R S

BY the death of Alan Archibald Campbell Swinton on Feb 19, scientific research loses one who has done valuable work especially in X-rays and radio communication The third son of Archibald Campbell Swinton of Kimmerghame, Berwickshire, he was born on Oct 18, 1863 His father was a professor of civil law in the University of Edinburgh from 1842 to 1862 and was also Brigadier-General in the Royal Company of Archers He could prove direct descent from the Royal House of Scotland Prof Swinton's second son was Captain George S C Swinton, who was chairman of the London County Council in 1912 and chairman of the town-planning committee of the new city of Delhi He was also Lord Lyon King of Arms Prof Swinton's sister was the mother of Archbishop Lord Davidson

When a child, Alan Campbell Swinton showed a bent towards engineering An oil painting of him when aged nine, with a steam engine in his hand, was shown at the Royal Scottish Academy

Reviews

"The New Britannica"

The Encyclopædia Britannica a New Survey of Universal Knowledge Fourteenth edition In 24 volumes Each volume about 1000 pages (London The Encyclopædia Britannica Co, Ltd, New York Encyclopædia Britannica Inc, 1929) Cloth, £27 16*s* 6*d*, Half Morocco, £36 17*s* 6*d*, Three-quarter Morocco, £49 10*s*, Full Morocco, £69, Library Bookcase Table included

IN the opening paragraph of the preface to the fourteenth edition of the "Encyclopædia Britannica", the editor at once strikes the note of innovation which to coming generations will be the distinctive mark of this issue of a great publication He points out that, from the time of d'Alembert's preface to the great French "Encyclopedie" of the eighteenth century, it has been customary to prefix to encyclopædias a general dissertation upon 'the body and divisions of knowledge, its life and advancement, its inspiration and utilities" His own task he has conceived differently Such a unifying impression, he holds, and all will agree justly, has passed beyond the power of man He aims now at stating what is the spirit animating "this newest design", the scope of its contents and the methods by which the whole has been formed

'Monumental' is a word which has been sadly overworked in relation to the heavier literature of to day and yesterday, but no other is more readily applicable to the "Encyclopædia Britannica" With equal propriety it may be termed "more lasting than brass" Each successive edition falls out of date as the volume of knowledge increases, but each remains a landmark in the progress of man towards the completer conquest of his environment—not in the sense merely of his control of material conditions, but in the spiritual knowledge which ultimately informs all interpretations of the universe and its component parts, however much we may try to anchor them to earth with such labels as 'materialistic' and 'mechanistic'

In every great encyclopædia which is worthy of that name the spirit of the age takes on bodily form This is as true of the fourteenth edition of the 'Encyclopædia Britannica' as it was of the ninth and as it was of the first edition one hundred and sixty years ago Yet if we would contrast to day with yesterday, or perhaps more aptly the day before yesterday, we should look to the great "Encyclopédie" of Diderot and d'Alembert rather than to the "Britannica" That momentous French compilation of the eighteenth century sounded the death knell of the old regime It focused the scepticism of which Voltaire was the protagonist, the idealism of which Rousseau was the prophet, and the realism of Montesquieu and the natural philosophers it gave general currency to ideas which were to be a driving force in philosophy, in science, in literature, and in politics throughout the French Revolution and the troubled times in Europe of the first half of the nineteenth century

This spirit still lives Yet if we seek to draw a parallel in the conditions of this newer world and the old, it is the ninth edition of the "Encyclopædia Britannica" rather than the fourteenth which we would compare with the "Encyclopédie" Just as the latter inspired the French Revolution and its immanent philosophic ideals, the ninth edition paved the way to a revolution in every department of human life which was no whit less far reaching than the political upheavals of the eighteenth and early nineteenth centuries, and of which no one can yet foretell the full effect When the publication of the ninth edition began in 1875 the world was still orthodox The ideas of Darwinism had not yet gained currency their full implication—all that body of healthy scepticism for which they now stand to us—had not been generally perceived, much less had their ramifications been worked out The leaven had only begun to leaven the lump Fourteen years later, when publication was complete, the viewpoint of science and philosophy, of literature and art, was changing from the static to the dynamic We are no longer in the fixed conditions of a settled universe Once more the inquirer stands with the first prophet of evolution in a world of flux and can exclaim with Heracleitus πάντα ῥεῖ

Yet the very moment in which the philosopher seemed to grasp the key which would open the door to the secrets of the universe witnessed the shattering of his hope The spirit of inquiry which had been released by the break up of the orthodox world, turned to rend its deliverer On one hand, the sum of knowledge rapidly passed beyond the comprehension of a single synthetic scheme on the other, the teleological concepts which had been coupled with the evolutionary theory failed to make good their validity—a fortunate chance, can it be called, otherwise had the world of intellect been confined by an idealism as sterilising in the long run as the orthodox conceptions of the mid nineteenth century

It is almost a commonplace of criticism to regard the generation which has followed the later years of the nineteenth century as materialistic A more just interpretation of the intense preoccupation with facts which is perhaps the most salient characteristic of that generation would attribute it rather to the extension of scientific method to all branches of knowledge Most marked, perhaps, is the application of that method to departments of life which, if hitherto regarded vaguely as subject to general laws, under a regime of *laissez faire* had in practice been left to a more or less informed employment of the method of 'trial and error'

In those sciences of which the subject matter is susceptible of study by experiment, there has been in the present generation an enormous increase in the volume and intensity of research But in the biological sciences, more especially in those which bear upon human life, the range of experiment is limited Here, however, research has been prosecuted with no less activity This has been rendered possible by a continually increasing appreciation of the degree to which observation can be made to serve the purpose of experiment By a widely extended record of facts observed in varying conditions which afford material for contrast and comparison, methods of study have been formulated analogous to the 'control' of the experimental laboratory It is in the light of this conception that there has grown up in little more than a generation the vast body of knowledge which is comprised in the study of heredity and that, very slowly it is true, the study of genetics, of eugenics, of anthropology, and of sociology are collecting facts and formulating principles which are becoming more and more the background in the work of social welfare and to a degree in actual legislation The effect of scientific method in the attack on the problems of hygiene and public health is too obvious to need comment

It is, however, to the War that we must look for the most potent stimulus, both directly and indirectly, to the extension of scientific research and to the increased application of its results to the practical affairs of life The War was universal in its effect The struggle was not confined to the trenches, 'supply' was not merely a question of maintaining an army in the field There was no department in the life of the nation so remote that it was not vitally affected If chemical warfare was the most obvious province of research, it was one only of many Every effort was demanded from science to help to conserve and extend the resources of the nation in the vital services of life

For those who look to a scientific attitude of mind as an essential factor in the attack on the many and grave problems of this post War world, it is of the utmost moment that the significance of science during the War has not been entirely forgotten The diversion of practically the whole body of scientifically trained men in the country to the service of the nation made the public familiar with certain principles On one hand, it came to appreciate that scientific research, however apparently remote its object from practical affairs, still has its value, and, on the other, that even in problems in which science is not directly concerned, the scientifically trained mind and 'scientific method' in mode of attack minimise effort and offer the greatest promise of an ultimate solution Hence since the close of the War a change of attitude towards science has to be noted as an element in the formulation of popular opinion The age of reason, however, is not yet Polities still govern legislation But the attempt, for example, which is being made to formulate basic principles in accordance with scientific fact in questions so tinged with emotion as marriage and divorce is at least significant

We may appear to have wandered somewhat far from the "Encyclopædia Britannica", but these reflections occur inevitably when both its new form and content are considered It is a product and a reflection of its age as much as earlier editions have been At the present day science workers are overwhelmed with the volume of research Each becomes increasingly absorbed in his own restricted field Specialisation grows from day to day, and no one can hope to keep fully abreast with advances in fields other than his own The editors have therefore had a difficult task to perform The general essays, in their day highly valuable contributions to the advancement of knowledge, which

have been a feature of earlier editions, have tended to disappear In their place, greater subdivision, entailing a great increase in the number of separate articles, more detailed treatment, and an increased volume of specific information so far as consistent with due regard to the broader outline of each subject, are the salient features of the new edition Again, borderline territories between the sciences and the interrelation of different sciences, a conspicuous feature in modern research, have had to be adequately covered It is therefore no matter for surprise to find that the whole editorial organisation has been fundamentally changed in the preparation of the latest edition The editorial staff has been supplemented, in fact except in its highest functions superseded, by a body of departmental specialist editors Not only has this given an added guarantee of accuracy, it has ensured a fitting perspective within each department

A perusal of the list of associate editors reads like a ' ministry of all the talents " Without attempting to give a complete list, a few of the more suggestive names may be mentioned Prof Andrade is responsible for physics, Prof Barcroft for physiology, Dr Cloudesley Brereton for education Geography is in the hands of Prof H J Fleure Prof Julian Huxley is responsible for biology and zoology, and Prof G T Morgan for chemistry Mr T C Hodson edits archæology and anthropology, and Prof A S Eddington, astronomy It is unnecessary to pursue the list further This brief selection suffices for a taste of its quality In addition, as the 'Encyclopædia" is essentially a result of Anglo American co operation, a corps of associates, each a recognised expert, was organised in New York, thus effectually securing the full representation of American scientific achievement

Of the quality of the sections for which the associate editors have been responsible, and of individual contributions, we hope to speak in later issues For the moment it must suffice to say that the new organisation has fully justified itself As a work of reference and a source of information on points of detail, the value of the "Encyclopædia", speaking generally, has been much enhanced The illustrations alone in themselves are a store of information, and both from the artistic and technical point of view are a remarkable achievement It is, perhaps, hazardous to prophesy that this edition of the "Britannica" will be regarded as a permanent possession for generations to come, it will certainly long be regarded as a monument of technical excellence in book production

Bacteriology in Medicine

Medical Research Council A System of Bacteriology in relation to Medicine Vol 4 By H J Bensted, W Bulloch, L Dudgeon, A D Gardner, E D W Greig, D Harvey, W F Harvey, T J Mackie, R A O'Brien, H M Perry, H Schutze, P Bruce White, W J Wilson Pp 482 (London H M Stationery Office, 1929) 21*s* net

THIS volume is divided into seven chapters, of which the first four are devoted to the coli typhoid group of organisms All the writers have special knowledge of the subjects with which they have dealt, and the majority have had considerable practical experience in the medical aspect of the disease of which the bacteriology is described As would be expected, therefore, the articles are of a high standard Every chapter gives evidence of a very painstaking and weary search through, not only recent, but also somewhat ancient, literature, and some of the chapters must have involved an enormous amount of practical investigation, in fact, it is doubtful whether the book has not suffered to some extent by the publication of the results of elaborate researches which are more of academic interest than of practical scientific value That problems of scientific bacteriology are at present in a somewhat unstable condition is seen in several of the chapters, and it would, we think, have been better if the work of some of the researchers had been held back until more certainty had been attained

In the review of Vol 3, we criticised the position of some of the chapters, and even the desirability of including them in that volume The same unfortunate grouping is again manifest in Vol 4 The separation of the *Pasteurella* group and B *pseudotuberculosis rodentium* from the chapter on B *pestis* in Vol 3 is an example of this The close relationship between these organisms is admitted by the author He says, "Two bacterial species, B *pestis* and B *pseudotuberculosis rodentium* to which the Pasteurella are most closely related " This may be regarded as a small defect, but surely in a work of the standing of the present one, it is desirable that some definite arrangement of the material should have been made and that chapters dealing with very closely related bacteria should have been in one group, or at any rate in one volume, and not separated by chapters dealing with entirely different subjects

Chap 1 deals with *Bacillus typhosus* With his usual clearness and accuracy, Bulloch writes a very interesting, short history of the organism, and an

account of the practical diagnosis of typhoid and para-typhoid, by Perry and Bensted, will prove of great value to all who are dealing with the subject from the clinical side, though more detailed consideration of some points, such as the parts dealing with blood culture, would have improved it The main part of this chapter is by D Harvey, and it is a valuable contribution to the literature of typhoid fever There is nothing new about the article, but it is an excellent summary of a vast amount of original work by other workers The author has dealt very fully with all the important aspects of the bacteriology of this disease, and has not over-emphasised minor points It seems unnecessary, however, still to maintain the old statement, repeated in almost every text book on bacteriology, of the number and length of the flagella No one has a successful stain for them and the necessary manipulation must render a count and a measurement utterly valueless

Again, on p 18—" Blood At one time it was stated that the finding of Gram negative bacilli in the blood was a possible method of diagnosis of typhoid fever But it must be remembered that to obtain a successful culture it is, as a rule, necessary to take at least 5 c cm of blood It is obvious, therefore, that the chance of discovering a bacillus in a drop of blood is remote "

It is correct to say that the finding of the bacillus in the blood is a method of diagnosis, and surely no bacteriologist would misinterpret the statement in the way suggested in the latter part of the paragraph

Chap ii, on the *Salmonella* group, is by P Bruce White Most bacteriologists have worked on this group, and all such must recognise the enormous amount of work this chapter has demanded It is not merely a careful review of the very numerous communications on the subject, but much is his own experimental work That kind of work is very laborious and exacting, and the results are of a very high scientific value We find it somewhat difficult to appraise its real value, as so many points can only be fully appreciated by those who have themselves worked at the intricate details given in relation to the types, serology, etc, of this group of bacteria The chapter must be placed as one of the best, if not the best published statement of this group, and will remain a standard of reference for workers on bacteriology It would, we think, have been better if the details given on p 101 about the "H" and "O" antigenic variations had been given before the reference made to them on p 88 had been written

The pathology of these infections is dealt with very imperfectly and contrasts unfavourably with that of the organisms dealt with in the other chapters To many of those who are dealing with *Salmonella* infections the pathology is important, and they will get little information of value from this article The chapter would have been improved if this aspect of the infections had been dealt with by an author familiar with the clinical manifestations of the diseases caused by this group of organisms In spite of these defects, the value of this chapter to bacteriologists cannot be over-estimated

In Chap iii, on the dysentery group of bacilli, a short history is given by Dr Bulloch, and a brief article, containing the essential details on the production of toxin and antitoxin on the large scale, is written by Dr O'Brien Both are well done The rest of the chapter is divided between Dr Gardner and Prof Dudgeon The whole chapter gives a very complete account of the bacteriology of this disease A specially valuable feature is the full way in which practical diagnosis in infections with *B flexner*, *B shiga*, and *B sonne* is discussed

Chap iv, by W J Wilson and W Bulloch, deals with the Colon group and similar bacteria This chapter will prove of great value to all workers on the subject The information is exhaustive, the arrangement good, and the writing clear

T J Mackie, E D W Greig, and W F Harvey have contributed Chap v, on the cholera vibrio and related organisms The history is again by W Bulloch and no comment is necessary Various aspects are dealt with very fully by the different authors There seems to have been a lack of close co operation between the authors, and the statements made by each are not always in agreement To take only two examples in the examination of water, Greig emphasises the importance of taking surface water for examination Mackie makes no reference to this important fact Greig and Mackie, in dealing with selective media for enrichment, give, in the main, entirely different methods Apart from points of this kind, the whole article is well written and is very accurate and full, and is the work of men who have had considerable practical experience in the bacteriology, epidemiology, and diagnosis of this disease The discussion of immunisation in this disease, by Dr Harvey, is a valuable addition to the chapter With the exception of a few minor points, the part by Greig on the pathogenic action of these bacteria is in keeping with the general excellence of the chapter

Chap vi is by H Schutze I have already referred to the misplacing of this chapter It is perhaps the most unsatisfactory part in the book,

not, however, because of the material and its manner of presentation, but because of the present unsatisfactory grouping of these organisms Dr Schütze had made the best of the material at his disposal

Taken as a whole, the volume under notice will be welcomed by all bacteriologists It should find a place in every medical library, and to the bacteriologist it will be a most welcome guide in all aspects of his work Authors and editors are to be congratulated on this production J M BEATTIE

Petroglyphs of California and Adjoining States

University of California Publications in American Archæology and Ethnology Vol 24, No 2 *Petroglyphs of California and adjoining States* By Julian H Steward Pp 47 238 + plates 22 94 (Berkeley University of California Press, London Cambridge University Press, 1929) 2 50 dollars

THIS publication is issued by the Department of Anthropology of the University of California It contains much that is of great interest to the student of primitive art, for it is concerned with a quantity of drawings which occur throughout California, being mostly executed on vertical rock surfaces There are both carvings and paintings, consisting for the most part of highly conventionalised figures of men and animals as well as what can only be classed as geometric patterns, and the whole forms a most interesting art group

Although the rock drawings of California itself are the author's chief concern, he has included in his survey those found in neighbouring States, since, naturally, modern political boundaries did not affect the primitive artists After a brief introduction, there follow short accounts of nearly three hundred sites where drawings occur These are largely based on materials (now in the care of the Department of Anthropology at the University) which were generally the contributions of private individuals The author has, however, studied a number of sites himself and his work is far from being purely one of compilation Next an analysis of the art is given, and the various types of figures to be found are duly classified Distribution maps show that while certain types of figures occur throughout the area, others occupy a more limited field The paintings, it appears, are almost entirely confined to the south west of the area under discussion

This analysis probably makes the most interesting reading in the whole volume The human form is represented again and again, and many of the conventions and symbols used in similar art groups in the Old World are to be observed here too Naturally, this does not necessitate any cultural connexion between, say, the Copper Age artists of southern Spain and these American draughtsmen of a probably very different date But it is interesting to note in the New World a similar desire to symbolise and, resulting therefrom, the occurrence of very similar symbols This is not difficult to explain, however, for conventionalisation in the sense in which we are using the word means the selection and emphasis of certain salient features in the object to be represented and the suppression of all unessential details For example, in the much older Upper Palæolithic art, conventionalisation also occurs, and such an object as a horse's head, seen 'full face', is represented as a trident like figure—to such an extent has the dropping out of detail reduced the picture—and we are left with two ears and the mane (the central prong of the trident) and length ! It is therefore not unnatural to find that, given the desire to conventionalise the figure of a man, certain types of symbols appear in widely separated parts of the world After all, there are only a limited number of symbol forms to which the human shape can be reduced when treated in the manner just described

The author hesitates to regard some of the symbols figured on p 184 as being human form derivations, but many of them can be matched in the Copper Age art group of Spain with figures which undoubtedly represent men and women Certain other figures were, he suggests, phallic symbols He may be right, but a simpler explanation would seem to be that they are merely drawings of human beings in which the sex is indicated Every Greek statue is not a phallic representation because the sex is obvious The animals are, of course, more difficult to 're naturalise', but some of the species indicated—including sheep—can be recognised

The geometric patterns include zigzags, concentric circles, spirals, etc These are of an especial interest, though once again correlations with similar figures in art groups in far off parts of the world are rash and unwarranted—the number of *simple* geometric designs conceivable being very limited In any case, however, the Spanish and North African counterparts of these geometric designs show differences which were not so apparent when we were considering the conventionalisations from life

The author next considers the meaning of the art and its age As regards the former, he rejects the notion that the drawings were purely decorative in intent, or executed to while away a chance half hour They are often found far away from settlement sites, and the Indians to-day, though professing to know nothing about them, nevertheless regard them with awe On the whole, he seems to consider that they were connected with initiation ceremonies which take place at the age of puberty among many primitive peoples The question of the age of the drawings cannot be answered with any certainty Most of them probably date from the Basket Maker to the Cliff Dweller or early Pueblo culture The drawings of the Santa Barbara district (where many of the paintings are situated) have, however, a very fresh appearance and would seem to be the most recent in origin

In conclusion, there are no less than 94 half tone plates It is perhaps a pity that the carvings were almost invariably chalked before being photographed The process of chalking is in general to be avoided for scientific purposes, since it allows the personal factor to come into the work Rock carvings will almost always photograph well at those times of day when the sun's rays strike the figures obliquely, and a certain proportion of such photographs would have been very welcome in this volume Altogether, however, this is a really excellent work, which should not be missed by students of American archæology or primitive art

M C BURKITT

The Geology of Great Britain

Handbook of the Geology of Great Britain a Compilative Work Edited by Dr J W Evans and Dr C J Stubblefield Pp xii + 556 (London Thomas Murby and Co, 1929) 24s net

THIS handbook is a new and enlarged edition of the volume dealing with the British Isles of the "Handbuch der regionalen Geologie", published in Heidelberg about twelve years ago The general plan of the work is the same as that followed in the German issue with the exception that Ireland is no longer included The chapter devoted to the geology of the Channel Islands is retained Seventeen geologists, all authorities on the particular subjects with which they deal, have contributed, and the task of editing the manuscripts must have entailed much labour, but the book makes a notable advance on the earlier volume, and the editors are to be congratulated on the successful completion of their work

As was to be expected from the names of the contributors, the chapters devoted to the description of the Pre Cambrian and Lower Palæozoic rocks are excellent summaries of the knowledge now possessed of these formations A few minor discrepancies, however, may be noted in reading the accounts, but their presence in no wise seriously affects the subject matter For example, readers would be enlightened if the phrase "the term Caledonian has come into use in Goodchild's sense" (p 31) were explained One reads later (p 142) that Goodchild used the term for a stratigraphical unit, whilst earlier (p 2) one finds the more familiar use of the term to denote a system of folding Again, some confusion is created by the use of the term 'southern Scotland' for southern Highlands (p 33), more particularly since an unknown outcrop of Dalradian in Devonian is shown on the map (p 37) as occurring somewhere near Lanark Less important is the statement that E B Bailey accepts the Moine gneiss as altered Torridonian rocks

The difficulty of keeping abreast with geological literature is probably responsible for the absence of any reference to the occurrence of rocks of Lingula Flags age in a borehole in Essex, and to the discovery of the pygidium of a trilobite (*Calymene* sp) in the Stiperstones Quartzite The specimen is now preserved in the Museum of Practical Geology, and an announcement of its presentation was made in 1918

It would seem that much further study is necessary before the classification of the rocks grouped under Downtonian is finally decided In the Silurian chapter, an excellent summary of the previous investigations is given under the heading Downtonian, with the provision that it is as yet premature to decide whether the rocks should be regarded as belonging to the lower part of the Devonian system or retained as the upper members of the Silurian In the brief description of the Downtonian in the Devonian chapter, however, we read that the Downtonian "may be considered to represent a passage from the Silurian to the Old Red Sandstone" (p 138) It is perhaps not necessary to make further comment on this question of classification at the moment, but my own experience of these beds on the Welsh borderland lends support to the view that the Ludlow Bone Bed forms a natural base to the Devonian System, as advocated by Dudley Stamp and other workers

By far the most notable contribution to the volume is that made on the Lower Carboniferous rocks It is concise, lucid, and informative, and

the author, besides incorporating a considerable amount of original work, has shown great skill in marshalling the results attained in England by many workers inspired by the earlier researches of Vaughan and Garwood. Geologists, both in England and Scotland, would, however, have welcomed a more up to date account of the Scottish Lower Carboniferous rocks. Much work has been done in Scotland since 1910, and there is, in consequence, a considerable body of palæontological evidence now available to permit a close correlation to be made with the corresponding rocks in England, despite the statement that an application of zonal methods to the Scottish Carboniferous is not possible (p. 224). There is every reason to hope that further study of the Calciferous Sandstone series of Fife and the Lothians will yield useful guide fossils, and the reviewer thinks it probable that the Rhynchonellids found by Kirkby in Bed VII., a limestone lying about 3350 feet below the Hurlet at Randerstone, St. Andrews, may represent the horizon of *Camarotœchia proava*. It is not without significance that algal remains are abundant about 100 feet lower in the sequence, particularly in Bed IX.

Respecting the Upper Carboniferous rocks, the succinct account of the Millstone Grit is equally valuable in presenting in summarised form the researches of Bisat and those of W. B. Wright and his colleagues. The zonal studies of *Goniatites*, initiated in Great Britain by Bisat, have already borne fruit in elucidating the somewhat complicated stratigraphical relations within the formation. The account of the Coal Measures is somehow less satisfactory. Although the chapter is a veritable store of information, it lacks the precision of other contributions. This is perhaps due to the absence of sections illustrative of the succession in each of the principal coalfields. The author makes full reference to the zonal work of Kidston, Arber, and Crookall on the palæobotanical side, and to the studies of Trueman, Davies, and Miss Dix, which have built up a sound scheme of classification based on the fresh-water Mollusca. No notice is made of the fact that the Mansfield marine band is a horizon that has been recognised in Scotland, Wales, and in other English coalfields outside Yorkshire and Nottingham. It may be of general interest to add that the great series of barren red measures in Ayrshire have recently yielded palæontological evidence which proves the presence of rocks of the Radstockian stage in this coalfield.

The rocks grouped under the Permian, Triassic, and Rhætic receive adequate treatment from their exponents. The writer of the Permian chapter has wisely avoided controversy by stating the connotation of the term Permian as used in his account. That there is a great need for further investigation of the Permian and Triassic strata in Great Britain is clearly revealed throughout the chapters. Thus, on p. 312 we are told that in the district of Mauchline "a volcanic group of strongly alkaline character" is associated with red sandstones, assigned by some authors to the Permian and by others to the uppermost part of the Coal Measures, whilst on p. 335, under the heading of Trias, the same sandstones are referred to the Permo-Trias. These difficulties serve to emphasise the important fact that, without the aid of sound palæontological data, little reliance can be placed on lithological characters as a means of correlation.

In the Rhætic chapter the customary clear diction of the author seems to have forsaken him in writing the second sentence on p. 341. It is so long and involved as completely to obscure its meaning.

The Jurassic rocks are dealt with in a more extended manner than was possible in the first edition, and the zonal succession established in the various groups by the studies of various workers, notably the late S. S. Buckman, the Nestor of British palæontologists, is set forth on four correlation tables. Despite the small discrepancies which may be corrected before re-issue, the tables will prove a boon to students. Readers would be helped, however, if the English divisions were placed in a column to show their approximately equivalent stages, and so avoid the need to make reference to p. 361 where they are tabulated. One is surprised to read that the mutual relations of the Hartwell Clay are still uncertain. The chapters on the Cretaceous and Tertiary rocks are beyond reproach and deserve praise.

Considerable portions of the account of the phenomena associated with the glaciation of Britain taken from the first edition have been incorporated in the present volume; but the contributors have brought to bear on the subject a wide experience and knowledge gained in Great Britain and other countries. This is particularly well shown in the description of glacially disturbed deposits and in the discussion of glacial tectonics. The views expounded will be new to many readers who have not had access to the authors' papers.

In spite of the comprehensive way the subject has been dealt with, notable work in some areas has been entirely overlooked. London geologists, for example, will search in vain for any reference

to Lake Oxford and the Goring Gap The admirable investigations of Dr Sandford in the Oxford district are not mentioned in the chapter, although a full account of his studies has been given in the Oxford memoir issued by the Geological Survey in 1926 Again, the fine work of Dr Bremner on the glacial deposits of the north east of Scotland is passed over, as is also the results of a gravitational survey over the buried Kelvin Valley at Drumry, an account of which was read at the Glasgow meeting of the British Association In the latter instance it is possible that the chapter may have been set up in type at the time

The descriptions of the igneous rocks in the Ordovician and later formations are much the same as appeared in the first edition, but the author has in some cases availed himself of recent work to bring his account up to date

Valuable features of the volume are the correlation tables appearing in most sections and the bibliography appended at the end of each chapter While the lists of works given are not claimed to be complete, they have been compiled with care and will be of great service to all workers There is an excellent index containing more than 5000 entries J PRINGLE

The Parachor

The Parachor and Valency By Dr Samuel Sugden (Twentieth Century Chemistry Series) Pp vii + 224 (London George Routledge and Sons, Ltd , 1929) 12*s* 6*d* net

IN 1923 a short paper by McLeod was published in the *Transactions of the Faraday Society*, in which a simple relation between density and surface tension was disclosed, namely

$$\gamma = C\,(D-d)^4$$

where γ is the surface tension of a liquid, whilst D and d are the densities of the liquid and of its saturated vapour at the same temperature The significance of this formula was that the influence of temperature on surface tension was now represented in a rational way, since the surface tension was made to vanish at the critical point, when the densities of the liquid and of its saturated vapour become identical, whereas the formula of Ramsay and Shields, in which the density of the vapour was ignored, makes the surface tension vanish 6° after the critical temperature is reached

Up to this point the surface tension plays the leading rôle, but the author of the present volume discovered a much more far-reaching application of McLeod's formula Thus, if the surface tension γ divided by $(D-d)^4$ is a constant, it follows at once that $(D-d)$ must be a constant if divided by $\gamma^{\frac{1}{4}}$, in other words, the influence of temperature on specific and molecular volumes can be eliminated completely if D is replaced by $D-d$ and then divided by $\gamma^{\frac{1}{4}}$ The function $M\gamma^{\frac{1}{4}}/(D-d)$, which Sugden calls the parachor, is in fact a molecular volume, M/D, which has been corrected with the help of the surface tension for the overwhelming influence of an internal pressure ranging in typical cases from 1500 to 60,000 atmospheres, and is thus made independent of the temperatures at which it is measured It therefore replaces, with greatly enhanced efficiency, the old molecular volumes, which Kopp attempted in vain to regularise by measuring them at the boiling point of each liquid instead of at the atmospheric temperature These old molecular volumes made only a feeble pretence at being additive functions, since different atomic volumes had to be assumed for oxygen in alcohols, ethers, ketones, etc , but the molecular parachors need only a single atomic parachor for each kind of atom, and a single constant each for the double and triple bond, or for the formation of a ring of *n* atoms, whatever the nature of the atoms which are joined by the multiple bonds or included in the ring It is, indeed, entirely pleasing to encounter a function which vindicates forthwith the Kekulé formula for benzene, even though it admits the existence of an unexplained anomaly in the carboxyl group

The present writer has a peculiar reason for thinking well of the parachor, since it provided the first experimental verification of his contention that a double bond need not always be a double covalence or a double electrovalence, but may sometimes be 'mixed' (or 'semi polar' as Sugden has called it), consisting of a covalence and electrovalence superposed on one another This vindication was particularly welcome in view of the fact that the first paper on the subject had the honour of being consigned to the archives of the society to which it was sent, although the Faraday Society found no difficulty in giving publicity to the 'mixed double bond' as a legitimate extension of J J Thomson's theory of 'intramolecular ionisation' The even more conclusive proof which resulted from the resolution of semi-polar compounds into optically active components, and the further evidence derived from Dr Bennett's fascinating studies of stereoisomerism, are set out fully in the volume now under review

Whilst the discrimination of double bonds, as being either nonpolar or semi-polar, was the first

and perhaps the most important experimental achievement of the parachor, this function is capable of such a wide range of applications that most of the outstanding valency problems in chemistry provoke at once a question as to the verdict which will be given when data from the parachor become available In some cases the strictly additive character of the parachor precludes the possibility of an answer Thus it makes no difference to the parachor whether two double bonds are 'conjugated', with one single bond between them, or are more widely separated in the molecule, since there is no echo here of the anomalies which are called to mind by the phrase 'optical exaltation', moreover, the conversion of two double bonds into one triple bond makes no difference to the parachor, so that equal values are given by systems such as $CH_3O\ C{\equiv}N$ and $CH_3N{=}C{=}O$ There are, however, many cases in which the formation of a ring in place of a double bond can be detected, and the later studies of Sugden and his colleagues have revealed an array of positive and negative anomalies which is amply sufficient to keep the parachor in the limelight for many years to come

Sugden himself has found an explanation of several large and important groups of negative anomalies by calling to life the single electron bond, which has proved so attractive to students of 'partial valencies' ever since G N Lewis declared that it takes two electrons to make a bond Lewis's contention appears even more convincing at the present time, when physicists have explained that pairs of electrons spinning in opposite directions are required to form a stable electronic system in molecules as well as in atoms or ions, but Sugden has worked out a series of formulæ which are at least consistent with one another and with certain postulates as to the parachor value to be assigned to this hypothetical type of linking

Whilst, therefore, both chemists and physicists may look with dislike on odd electron bonds, it must be admitted that all the alternatives which have yet been devised have been turned down as a result of the experimental work which the author has carried out in order to test them Unbelievers can, therefore, only take refuge (like the reviewer) in a barren agnosticism, hoping that a function which cannot distinguish between one triple and two double bonds may have failed equally to discriminate between a pair of single-electron bonds and some more plausible electronic configuration

Here and there the author is perhaps too confident in his statements Thus, it is not true that diborane, B_2H_6, "contains only twelve electrons" (p 95) and that therefore "the presence of singlet linkages must be admitted" (p 130), when there are really 10 K electrons and 6 L electrons available for joining the 8 atoms, and it is only when certain postulates have been accepted, and the possibility of alternative interpretations has been finally denied, that it can be admitted, in the case of basic beryllium acetate, that "the parachor shows conclusively that the singlet formula is correct" (p 146) Phrases such as these are, however, not easily avoided when describing the results of a battle in which present victory has been won, and the risk of retreat in the future is still too remote to justify the qualifications and reservations which would appear necessary in less favourable circumstances

If Dr Sugden had merely collected his published work into a monograph, and discussed its implications in greater detail than is usually possible in original papers, he would have rendered a very useful service both to his colleagues and to their more advanced students He has, however, done much more than this, since the volume now under consideration also contains chapters on "The Liquid State", on 'Associated Liquids", on "Atoms and Spectra', and finally on "The Quantum Theory of Shared Electrons" These are written in the masterly manner of one whose knowledge comes from original sources, and has not been distorted by transmission through intermediate text books For this reason the book can be commended to advanced students who are not specially interested in the parachor, but who would like to keep abreast with modern research in atomic physics Moreover, even the earliest references appear to have been consulted in the original, with the result that the foundations of our modern conceptions are sometimes unexpectedly laid bare The book is, in fact, exceptionally well filled with information, even for a hardened reader of physico chemical literature, and familiar facts and theories are often revealed in an unfamiliar light, and with unwonted clearness On the other hand, the indices and subscripts are printed in such small type that they are often defective or illegible The rather bewildering electronic formulæ which the author has adopted have also given a lot of trouble to the printer, whose symbol for benzene is a very battered hexagon It is also curious that, although the symbol for the parachor is given in the first instance on p 30 as [P], it is nearly always printed afterwards with a superfluous (and unintended?) full stop inside the bracket

In conclusion, since the book deals at length with the methods of determining surface tension, it is difficult to resist the temptation to bring together two phrases in reference to the method of deducing tension from the weight or volume of falling drops "Iredale has criticised the formula used by Harkins and his co workers, and suggests a return to an equation given earlier by Worthington" Nevertheless, "the equations of Harkins and Worthington are really identical, for one can be deduced from the other without introducing any approximations" T M LOWRY

Unofficial Pharmacopeias

(1) *The Extra Pharmacopœia of Martindale and Westcott* Revised by Dr W Harrison Martindale Nineteenth edition In 2 volumes Vol 2 Pp xxxviii + 759 (London H K Lewis and Co, Ltd, 1929) 22*s* 6*d* net

(2) *Pharmaceutical Formulas* P F Vol 1 being *The Chemist and Druggist* Book of selected Formulas from the British, United States, and other Pharmacopœias, together with Non Official Formulas from various Sources Tenth edition, entirely revised and rewritten By S W Woolley and G P Forrester Pp xvi + 1146 (London *The Chemist and Druggist*, 1929) 15*s*

THE last British Pharmacopeia was published in 1914, a new one is now in preparation and is due to appear in 1931 In the interval, the United States has produced two official pharmacopeias, the ninth in 1916 and the tenth in 1926 The long intervals between successive editions, the wise conservatism of pharmacopeial commissions, and the limitations imposed upon pharmacopeias by their legal status, make it inevitable that there must always be a huge materia medica which does not find official recognition, and this is the happy hunting ground of the compiler of dispensatories, formularies, pharmacopeial companions, and in general of the mass of literature which may be grouped together as 'unofficial pharmacopeias' Such literature is indispensable to the busy pharmacist and medical man, as is evident from the fact that the two books now under review are in their nineteenth and tenth editions respectively They both supplement the official pharmacopeia and they are complementary to each other

(1) The "Extra Pharmacopœia" of Martindale began as a modest pocket volume of 300 pages in 1883, and is now issued in two volumes of 1207 and 759 pages respectively, and even this increase in size is not sufficient to include all that the author would like to put into it, for he is now finding it necessary to refer the reader back to information given in previous editions but omitted from this one The two features which have contributed more than anything else to the popularity of the book are the author's gift of compressing the contents of a paper into a few lines or a few words, and his conscientious industry in searching the literature and providing the reader with references to papers or abstracts in readily accessible journals The division into two volumes took place in 1912, and since then Vol 2 has been a compact manual of chemistry designed to meet the everyday needs of the pharmacist and the medical man These needs are very varied, and consequently the volume deals with such subjects as indicators for volumetric analysis, the analytical recognition of organic substances used in medicine, water analysis, embalming, composition of proprietary medicines, mould inhibition by preservatives, etc The author is one of those fortunate people who is not hypnotised either by authority or the printed word, and his remarks on some fashionable doctrines and processes are shrewd, sometimes piquant, and invariably tinctured by a genial conservatism Like all editions of this work, this edition is remarkably free from errors and is well up to-date

(2) "Pharmaceutical Formulas" is a book of entirely different type, being almost wholly concerned with the compounding of drugs, a subject with which readers of NATURE probably do not desire to extend their acquaintance beyond that casual and involuntary knowledge forced upon them by occasional illness The real public service rendered by the issue of a book like this may perhaps be illustrated by reference to such a substance as acriflavine Most organic chemists are aware that the discovery of this material marked a distinct advance in chemotherapy, but few realise that its practical use in medicine depends upon the exercise by the pharmacist of his art, so that it may be presented to the medical man in a form suitable for application In this volume five preparations of acriflavine—solution, lotion, emulsion, paste, and poultice—are described, and from them the busy practitioner can select the form best suited for any particular case The book gives the same kind of information for each and all of the hundreds of materials which modern science has placed at the service of medicine

A pleasant feature of the volume is its insistence upon the historical aspect of the pharmacist's art and the brief but wholly delightful note upon 'honey water' which George Nelson, author of

"The Compleat Course of Chymistry", compounded for King James II is an example of how such things should be written It is a little surprising to find that "Confectio Damocratis", invented by Mithridates the Great, 134 B C, may still figure in modern medicine It is an ingredient of the original 'Warburg's tincture', a mixture still used by some European residents in the tropics, and it may be regarded as the real ancestor of the aromatic confection invented by no less a person than Sir Walter Raleigh, and which in a modified form is still official in the last edition of the British Pharmacopeia T A H

Birds and their Ways

(1) *The Cowbirds a Study in the Biology of Social Parasitism* By Dr Herbert Friedmann Pp xvii + 421 (Springfield, Ill, and Baltimore, Md Charles C Thomas, London Baillière, Tindall and Cox, 1929) 27*s* net

(2) *Birds and Green Places a Book of Australian Nature Gossip* By Alec H Chisholm Pp xiv + 224 + 50 plates (London and Toronto J M Dent and Sons, Ltd, New York E P Dutton and Co, Inc, 1929) 15*s* net

(3) *The Birds of South East Devon being a List of those Species known to visit that part of the County including and lying to the East of the Exe Valley* By Lewis R W Loyd Pp 176 + 6 plates (London H F and G Witherby, 1929) 10*s* 6*d* net

(4) *The Birds of Ayrshire* By E Richmond Paton and Oliver G Pike Pp xxi + 228 + 25 plates (London H F and G Witherby, 1929) 21*s* net

(1) THAT form of parasitism which is familiarly exemplified by the common cuckoo in Europe, and by some other members of its family found in Europe, Asia, and Africa, occurs also among the cowbirds of the New World, among the weaver birds and the honey guides of Africa, and in one South American species of duck As it doubtless originated separately in each of these diverse groups, it constitutes a very remarkable instance of parallel evolution Next to the cuckoos, the cowbirds are the best known of the groups, and Dr Friedmann's important monograph brings together the existing information as to their reproductive habits, and adds to it the results of his own intensive observations

The cowbirds belong to the family of hangnests, closely allied to the finches There are seven species, in three genera, and six of these belong either to South or Central America the remaining species is widely distributed in the northern continent Two of the species are rarities known only from a few specimens, but the habits of the other five present material for an interesting comparative study

The bay winged cowbird of South America is parasitic only in that it lays in other birds' nests, taken by force or found disused If necessary, moreover, it builds for itself, and in any case it incubates its eggs and rears its young in quite a normal manner The screaming cowbird is truly parasitic, but its sole victim is the preceding species! More than one egg may be laid in the same nest, and there is no removal of eggs of the rightful owner The shiny cowbird, widely distributed over South America, victimises many species, but its parasitic habit is poorly developed and somewhat haphazard in its operation Very many eggs are laid, and of these the majority are wasted the eggs of the victims are frequently destroyed, but so also are eggs of its own species on occasion, so that this cowbird itself exercises a check upon its increase in any locality The North American cowbird has the parasitic habit better developed and lays a small number of eggs to good purpose the species which it has been known to victimise number a hundred and fifty eight, and individual birds, unlike cuckoos, show no very definite specificity in their choice of victims The red eyed cowbird of Central America is parasitic upon a limited number of species The rice grackle, a close ally of the true cowbirds, is also parasitic

As with our common cuckoo, the young cowbird usually survives at the expense of the offspring of its foster parents These are not ejected but are trampled or starved to death in the struggle for food Young screaming cowbirds, however, live in amity with the young baywings belonging to the nest this is paralleled in the Old World by the case of the great spotted cuckoo and the magpie

Dr Friedmann's monograph is a mine of information on the reproductive habits of cowbirds, but it is not a very readable book except for the serious student A more adequate general survey, summarising the systematic accounts of the several species, would have added greatly to its value, and the brief final chapter discussing the evolution of parasitism might well have been amplified There are some curious mistakes, as in the naming of the races of the North American species on page 152, and in the description of the diagram on page 263

(2) Mr Chisholm's book is of a very different type It is frankly a collection of 'Nature gossip'

rather than a contribution to science, but the author has the advantage of dealing with an avifauna of which little of a popular kind has been written, that of Queensland, and he describes the habits of many strange and wonderful birds which the reader in Great Britain knows, at most, only from captive or museum specimens Mobs of emus running on the great plains, the curious bee like swarming of the wood swallows, the rare paradise parrot nesting in termites' mounds, the cradle nest of the fairy warbler, the truly extraordinary habits of the bower birds these are among the subjects on which Mr Chisholm discourses pleasantly, weaving his account of the birds into the story of his personal experiences in search of them

(3 and 4) The remaining two books on our list come within the category of district avifaunas Works of this type fulfil two functions in the first place, they are of local interest, and, in the second, they provide valuable material for the compilers of books on the birds of the country as a whole Neither of these works comes up to the very highest standard for this class, but both are competent and useful contributions Mr Loyd is at a disadvantage in dealing with an area of which the limits are not recognised, and he does not always observe them himself He also encumbers his accounts of the local status of each species with brief general remarks which are inadequate for any purpose and irrelevant to the special object in view The work of Messrs Paton and Pike contains some very beautiful photographs of birds, although here again relevance may be questioned

Evelyn's "Fumifugium"

Fumifugium By John Evelyn, of Balliol College, Oxford, in 1661 Now reissued as an Old Ashmolean Reprint in the Year of the refacing of the Old Ashmolean Museum, which, like 'Fumifugium', was dedicated to King Charles II, founder of the Royal Society Pp viii + 49 (Oxford Dr R T Gunther, Folly Bridge, 1930) *2s 6d*

VOCAL as have been the protests against the emission of smoke and fumes from the chimneys of electric power stations in London, when one reads No 8 of Old Ashmolean Reprints, the "Fumifugium" of John Evelyn (1661), these modern protests seem couched in language mild and restrained compared with the diarist's wealth of obloquy and sustained invective against the effects of burning of coal by brewers, dyers, lime-burners, soap- and salt-boilers, and other private traders Additional picturesqueness is obtained, not by the modern method of pictures showing the pall of smoke over our cities or the corrosion of stonework, but by lurid quotations from the classics to heighten the condemnation of "that Hellish and dismal Cloud of Sea Coale" with its "fuliginous and filthy vapour, corrupting the Lungs", causing the City of London to resemble rather the "Suburbs of Hell than an Assembly of Rational Creatures and the Imperial Seat of our incomparable Monarch" Truly John Evelyn was a man before his time, and his "Fumifugium" characteristically not only describes the grievance, but also indicates the remedy and suggests an amelioration

Writing so soon after the Restoration, Evelyn philosophises on the effects of pure air, contrasting the proneness to rebellion of northern nations, with the more constant and steady temper of the inhabitants of lands nearer the tropics His commendation of air "which is cleare, open, sweetly ventilated and put into motion with gentle gales and breezes" would meet with the approval of Prof Leonard Hill On the other hand, he recognises that while the effects of ill conditioned meat may be mitigated by cooking, poisoned air insinuates itself into the vital parts immediately An eclipse, he declares, darkens the attributes of the otherwise incomparable City of London, on the situation and advantages of which he writes a fine panegyric, and this, not from the "Culinary fires", but from the "Tunnels and Issues" of the aforesaid traders giving off "that pernicious smoake which sullies all her glory superinducing a sooty Crust or Furr upon all that it lights, spoyling the moveables, tarnishing the Plate, gildings, and Furniture and corroding the very Iron bars and hardest Stones with those piercing and acrimonious Spirits which accompany its Sulphure" Further, it kills flowers, fruit, and bees, so that they can no longer thrive in the neighbourhood of the Strand, unless on such occasion as when coals were scarce by reason of the blockade of Newcastle in 1644

Worst of all, those who repair to London become immediately afflicted with divers ailments of which detailed and picturesque description is given "For is there under Heaven such Coughing and Snuffing to be heard, as in the London Churches and Assemblies of People, where the Barking and the Spitting is incessant and most importunate?" In the current of his invective, Evelyn is carried

somewhat to overstate his case when he affirms, "that it is not the Dust and Ordure which is daily cast out of their Houses but this continual Smoake, which renders the Streets of London dirty even to a Proverb"

In Part 2, Evelyn suggests the removal to a competent distance of factories giving off this evil smoke, a remedy which, however suitable to his time, would not be a solution in ours, when to domestic chimneys is attributed at least half of the smoke nuisance His selection of a site five or six miles distant from London "below the River of Thames" and apparently east of Blackheath, having regard to the prevailing winds and to water transport, is reminiscent of a phase in the present controversy Not only, however, should the smoking factories be removed, but he would also have banished churchyards, slaughter houses, gaols, chandlers', fishmongers', and butchers' yards to some place farther off, to prevent their distempering the air breathed by the inhabitants While these opinions leave no doubt as to Evelyn's fitness for his post of commissioner for improving the streets and buildings of London, it is to be feared that the opportunity afforded by the Great Fire was not seized on to give effect to his views and to Wren's ideas of town planning in the reconstruction necessary after that event

As might be anticipated in one so fond of gardening, Evelyn's scheme for "Melioration of the Aer of London" is "by Way of Plantations" In all low lying grounds near the city, and especially towards the east and south west, he suggests the plantation of belts of trees, lined with fragrant shrubs, while the spaces between the trees would be used as borders filled with sweet smelling flowers It is a pleasure even to read the list of these fragrant plants, and to conceive a London so small as to warrant his hope that "the whole City would be sensible of the sweet and ravishing varieties of the perfumes"

If Evelyn should return to day as First Commissioner of Works, what would he find in the conditions of the colossal city London has in the meantime become? Still the only partially solved smoke problem of the innumerable domestic fires, but let us hope soon the suppression of smoke and acids from the chimneys of large installations consuming coal, an increasingly healthy city through improved sanitation, rather than diminution of smoke, while perhaps the large area still given up to open spaces and parks would in some measure satisfy the author of "Sylva" and the "Compleat Gardener" R R

Hydrogen Ion Concentration

Hydrogen Ions their Determination and Importance in Pure and Industrial Chemistry By Dr Hubert T S Britton (Monographs on Applied Chemistry, Vol 3) Pp xiv+515 (London Chapman and Hall, Ltd, 1929) 25s net

THE introduction of the osmotic and electrolytic dissociation theories of solutions initiated, as is well known, a new era in the development of chemistry, and the new direction which was thereby given to the interpretation of chemical processes taking place in aqueous solution soon made itself powerfully felt also in the various branches of biological science and in the study of colloids The influence of different salts on colloidal matter and on the living cells of plants and animals became the subject of extensive and intensive investigation, and it was found that many of the observed phenomena could best be interpreted as due to the specific action of ions

Although it was to the action of the ions of salts that attention was at first mainly directed, it came to be recognised later that a position of special importance must be assigned to the hydrogen ion, and at the present day the 'acidity' of the medium is known to exercise a profound influence in operations and processes of the most diverse kind In volumetric and gravimetric analysis, in the precipitation of metal hydroxides, in soil analysis, in bacteriology, and in many industrial operations, the concentration of hydrogen ion is a factor of fundamental importance The determination and control of the concentration of hydrogen ion in a solution has, in consequence, received a rapidly increasing measure of attention in recent years In view of the important part played by hydrogen ion concentration and of the widespread necessity of obtaining a knowledge of the methods of determining and controlling the concentration of hydrogen ion, the present work by an author so competent and well qualified as is Dr Britton, is sure of a very hearty welcome

In the opening chapter, the author sets forth the theory of the electrometric methods of determining the concentration of hydrogen ion and adopts the ion concentration rather than the activity theory in the interpretation of electrode potentials The decision of the author in this respect has doubtless much to commend it in view of the public for which the book appears to have been written, but even a short discussion of the relation between the ion-concentration and the activity theories would have given an additional

value to the book Following on the discussion of the theory of electrode potentials there comes a description of the different kinds of electrode, and workers will find the author's account of the use of the quinhydrone and glass electrodes of particular interest and value The latter electrode, especially, is probably not so well known as it should be

In the succeeding chapters the author gives a very full, clear, and, on the whole, satisfying exposition of the practical applications of the electrometric and colorimetric methods of determining the concentration of hydrogen ion in solution, and points out the importance of such determinations in analytical chemistry, in the industries of tanning, brewing, baking, dyeing, etc, in the manufacture of paper, and in the refining of sugar The rôle of the hydrogen ion concentration in connexion with the purification of water, sewage disposal, and the fertility of soils, is also clearly discussed

In the volume before us, the third of the admirable series of monographs edited by Dr Howard Tripp, the author maintains the high standard of excellence set by the preceding volumes, and the work is remarkably free from printers' and other errors The book deserves to be, and doubtless will be, widely read, not only by advanced students of chemistry but also by those who are interested in the many and varied branches of science and industry in which the concentration of hydrogen ion plays a vitally important part A F

The Mechanical State of the Future

The Conquest of Thought by Invention in the Mechanical State of the Future By H Stafford Hatfield (Psyche Miniatures General Series No 26) Pp 117 (London Kegan Paul and Co, Ltd, 1929) 2*s* 6*d* net

A GREAT deal of thought is being concentrated to day on the general aspects, the underlying principles, and the probable future of our civilisation, which is supposed to be distinguished from all previous civilisations by a dominating industrialism gradually extending and deepening its hold throughout the entire social organism until it is complete master thereof, holding it under grievous thraldom, body and soul The present small volume, one of the Psyche miniatures now being published by Messrs Kegan Paul, attempts to show that this domination will take the form of a perfectly mechanised State in which practically every function and activity of the individual citizen will be a matter of regulated routine, and all his actions will be so guided and prescribed by the State that he will have little or no initiative or volition of his own, he will become a semi-hypnotised automaton, a machine slave The Machine Age will have arrived, not only in a literal sense wherein every part of manufacture will be done by machinery, but also in a wider and more figurative sense, wherein the machinery of government, of municipal organisation, and of industrial organisation will be so perfected that every circumstance or condition of the individual citizen will have its appropriate formula, and all that he will have to do to achieve a wholly successful life will be to apply formulæ as and when required, and with a minimum of conscious thought, effort, or mental disturbance of any kind Thought will have been conquered by invention

This is surely a strange paradox, an apparent contradiction in terms if, as one seems justified in assuming, invention is among the highest forms of thought, but what Dr Hatfield probably had in mind was the ultimate domination of society by extreme mechanisation based on invention, so that thought might almost seem to become superfluous, and he was probably looking about for a startling or impressive formula for expressing such a possibility But his definition of invention is not altogether satisfactory, he says

"The word invention is intended to cover the whole of the means by which humanity makes use of accumulated knowledge to eliminate the chances and difficulties of coping with the external world and to render it more agreeable"

This excludes a considerable field of invention which does not, directly or indirectly, aim at making the world more agreeable, and includes also a vast amount of invention which the author himself is perhaps contemplating under his definition, but which, instead of making the world more agreeable, has had precisely the contrary effect It may be, however, that the great majority of people would like to be relieved of all responsibility, to have nothing to do but obey rules and regulations, to lead a perfectly safe life sheltered from all the perversities of fortune or misfortune, to become volitionless automata But whether this is the best and highest and noblest destiny of the human race is another matter It is true that Dr Hatfield has made provision for original thought, scientific research and speculation, and original creative work of all kinds, in special segregated institutions, altogether apart from the common herd, and yet it may be questioned if this is quite the best consummation for science itself to aim at

However, it is only fair to say that the author is not speaking of the 'best', but the inevitable

On psychological grounds, possibly a plausible case might be made out for predicting some such culmination for our civilisation as that which Dr Hatfield presents, but it is a hopeless and gloomy picture, an ignoble destiny indeed for the human race, and it does seem that sufficient account has not been taken of all the relative factors and of any possible ameliorative or preventive measures that could be suggested If one could only regard the book as a very clever and subtle satire, a brilliant caricature of what we are coming to, the outlook would be less hopeless, but the author appears to be in deadly earnest, and he concludes his highly interesting and thought provocative thesis with the assurance that "All this is happening, so it seems to me, in so inevitable a manner that any argument concerning its desirability appears futile" There is thus no more to be said W G L C

Witches, Vampires, and the Devil

(1) *Witch Hunting and Witch Trials the Indictments for Witchcraft from the Records of 1373 Assizes held for the Home Circuit A D 1559–1736* Collected and edited by C L'Estrange Ewen, with an Introduction Pp xiii + 345 + 7 plates (London Kegan Paul and Co, Ltd, 1929) 21s net

(2) *The Vampire in Europe* By Montague Summers Pp xii + 330 + 8 plates (London Kegan Paul and Co, Ltd, 1929) 15s net

(3) *The Devil an Historical, Critical and Medical Study* By Maurice Garçon and Jean Vinchon Translated by Stephen Haden Guest from the sixth French edition Pp 288 (London Victor Gollancz, Ltd, 1929) 12s 6d net

THESE three books on witchcraft and cognate matters afford an interesting contrast in method The first deals objectively with facts, and thereby adds much to our knowledge, the third analyses familiar material from an original point of view as a psychological study, while the second may enlarge the reader's ideas as to the extent of human credulity even in these days

(1) Mr Ewen's book is a mine of information for the student A patient examination of documents in the Record Office has resurrected a large number of cases never previously noted, either by Hutchinson or by other writers on witchcraft Prof Notestein's list of 100 cases in the home counties is swelled to five hundred individuals and seven hundred indictments To these is added an appendix containing a list of further cases mentioned in contemporary documents, but not in the records of the courts Mr Ewen has also provided his readers with a complete apparatus for the study of the subject

In his lengthy introduction to the abstracts of indictments which forms the main section of the book, Mr Ewen surveys the whole machinery of witchcraft persecution, including the legislation from the earliest times, the courts in which trials might be held, and the procedure from information to trial The abstracts themselves are a valuable survey of the essential features of English witchcraft, and of the ends which the witch was supposed to have in view It is interesting to note that one witch was accused of digging up the skull of a dead man, an allegation also made in the Lancashire witch trial of 1612 One point of significance to emerge is that, so far as the home counties are concerned, the witchcraft persecution reached its highest under Elizabeth, and not under the Commonwealth, as is usually stated, another is the exceptional prominence of Essex as the home of the witch

(2) In "The Vampire in Europe", Dr Summers follows up his previous volume on the vampire by a collection of relations arranged under countries It affords plentiful material for students of the supernatural, but the author has had to interpret the vampire belief rather liberally to bring some of his data within the bounds of his subject Outside eastern Europe there is practically no evidence of the real vampire In ancient Greece and Rome, and still more in England and Ireland, until the literary efforts of modern times, the cases noted by Dr Summers are those of ordinary ghosts, often malignant, rather than of vampires The place of the vampire was taken by the were wolf In this volume Dr Summers appears to have abandoned his earlier methods entirely and to accept all stories at their face value as evidence—even fiction !

(3) "The Devil" is a useful corrective to Dr Summers It is also an answer, on one hand, to those who regard witchcraft as a surviving primitive religion, and on the other, to those who dismiss the evidence as due to, vaguely, hysteria As regards the first point, the authors hold that, beyond a few very general ideas, there is little of primitive magic in the witchcraft doctrine, except in so far as Innocent VIII gathered up much popular folklore in his famous Bull Nor was the devil a primitive concept Many hold that the concept of the devil was built up by the medieval church, just as the whole of the machinery of the witchcraft organisation was evolved by the Inquisition and judges through the medium of their examinations, which

were directed to elicit certain information Belief in the devil, on the other hand, is no evidence of delusion either in medieval or modern times It is an article of faith in the Roman Church, and before the explanation of hysteria can be applied to the facts, the border line of delusion must be fixed

The cases studied in the medico legal section of the book throws light on many manifestations of occultism They should be studied in conjunction with some of the cases of vampirism quoted by Dr Summers It must, however, be urged that the authors have paid too little attention to the survival of a strong element of real primitive belief among the people Can we fix a limit to the extent they were prepared to go in putting it into operation ?

The Trend of Applied Optics

Applied Optics and Optical Design By Prof A E Conrady Part 1 Pp ix + 518 (London Oxford University Press, 1929) 50*s* net

APPLIED optics, once a languishing subject, has now largely emerged from the phase of semi stagnation on one hand, and exploitation on the other, in which the outbreak of the War found it, and this book, contrasted with the predecessors of its class, emphasises the decided present-day trend of the science In his endeavour to confine his attention to ' real optics ', Prof Conrady has been influenced by some well-known criticisms of Prof Silvanus Thompson What was known as ' geometrical optics ' has, indeed, in more recent years, barely held its own against its critics, for it had certainly encroached to an unjustifiable extent upon neighbouring fields, at a period when un scrutinised criteria and false generalisations entered largely into its practical application The optical designer, examining his problems by the aid of such imperfect theoretical means, saw as through a glass darkly, quite unperceiving the imperfect nature and inadequacy for his purposes of the methods currently adopted and the shadow of fact which they revealed In later years the working of an ampler conception of the subject has removed the old inconsistencies and indicated fresh avenues of considerable possible development of the older plain theory

Broadly speaking, Prof Conrady proceeds by the conservative adoption of a type of semi-analytical method independently developed, and aims at providing a text book suitable for the use of students of the subject, in whom some rudimentary preliminary knowledge can be assumed The book opens with a chapter on " Fundamental Equations ", in which some of the simple, first order geometrical properties of symmetrical optical systems are considered and the old familiar com puting formulæ for the tracing of an axial ray attributed to Bessel are given Some further account of the simple Gaussian theory is given afterwards in Chapter ix on the general theory The student who realises at the outset the import ance of a thorough knowledge of the correct manipulation of the instrument of numerical cal culation will find useful guidance in the various practical hints and examples

Chapters follow in which spherical and chromatic aberration are considered upon the basis of trigono metrical calculation and leading up to the design of simple forms of achromatic object glasses, approximate algebraical expressions for these aberrations to facilitate the preliminary design being deduced from the fundamental equations and graphical methods being employed to advantage The chapter on spherical aberration is followed by a discussion on the physical aspect of optical images from an elementary point of view and the foundation of a system of optical aberrational tolerances, based upon the so called ' Rayleigh limit ', is laid, in readiness for application in suc ceeding chapters

Up to this stage, the student must be supposed ignorant of the aberrations and circumstances affecting extra axial image formation, and the following three chapters are devoted to this sub ject, which is approached by way of an application and extension of the previous algebraical third order treatment of axial spherical aberration of ray intersections applied to single surfaces Expressions similar to the aberration sums of von Seidel are thus obtained and employed as the basis of discussion with application to practice, the case of a system of ' thin ' components being especially considered Keeping in sight the appropriate needs of students, Prof Conrady clearly distinguishes three " Fundamental Laws ", these being generalisations of practical importance drawn from the third order theory of oblique pencils Direct computational experience of oblique aberration is postponed to a much later stage, where formulæ are given for the tracing of an oblique beam through any given axially symmetrical system Here it is sought to fortify the method by taking advantage of the foregoing analytical work in the interpretation of the results of computation

For the purposes of this first part, the third order analytical treatment does not seem to offer any outstanding intrinsic advantages over the

available alternative systems, or to exemplify how the subject, although not allowed to "become drowned in a vast mass of complicated algebra", may be presented to the student with any gain in clarity and perspicuity While so much remains to be done in the subject, it is a most lamentable fact that even upon common ground there should be no trace of an underlying unity in treatment or even in the notation employed by different writers This is in striking contrast to other progressive branches of applied mathematics, and as a result thereof, talented energies attracted to the subject in the past have been largely expended merely in independently evolving, in special notations, fresh metamorphoses of essentially the same theory, which have for the most part entered upon the world still born, destined to remain buried in the obscurer recesses of literature

The general form of Prof Conrady's algebraical theory must accordingly be familiar to the average reader Considered more in detail, the formulation is of the class in which the third order aberrations are regarded as depending upon the trigonometrical data specifying the passage of rays within the paraxial region in analogy to the simple ray tracing scheme for finite aperture, it is distinguished throughout by a decided practical bias, and also, however, by a somewhat laboured notation, which, apart from being a source of printing errors, is an obstacle to thought and progress It would be premature, on account of the apparently complementary nature of the forthcoming Part 2, to judge from the general point of view as to the comparative merit and utility of the system put forward

In an appropriate chapter the sine theorem is developed by extension out of the theorem of Lagrange The method has some didactic advantages Convenient formulæ for subsequent practical application are derived and proper emphasis is laid upon their inherent limitations, but considering the purpose of the work, the method would seem to be appropriate rather as a practical supplementation of a deduction in closer correlation with the physical aspect The book concludes with a chapter on the design of ordinary eyepieces as a fitting sequel to the foregoing theory, which pertains largely to telescope objectives

The general impression that remains is that the book would be of proportionately greater value, having regard for its intended purpose and audience, if the matter dealt with had been considerably compressed, for the work cannot be regarded as succinct Some other features cannot fail to impress themselves There is a noticeable tendency to looseness of expression The references to historical or contemporary work are few and far between and are merely of a cursory nature Differing favourably from most previous books on this subject, the ultimate workshop production is retained steadily in sight as an important factor influencing the course of the theoretical design of optical work The 'memoranda' following each chapter form a useful feature, but do not amply serve their purpose The book, as such, is well got up and appears at a time when there is a need for just this class of work In the present state of the literature, Prof Conrady's work will certainly form a noteworthy contribution

Big Game Hunting and Collecting

Big Game Hunting and Collecting in East Africa, 1903–1926 By Kalmán Kittenberger Translated from Hungarian Pp xix + 348 + 127 plates (London Edward Arnold and Co, 1929) 25*s* net

NUMBERS of men, first class old sportsmen, have lived long years and shot many lions in the bush regions of Central Africa, but unfortunately few of them have ventured or been able to put down their experiences on paper As often as not it is the man with more imagination than experience who ventures into print Mr Kittenberger, however, is one of the few During ten years in the lion country, shooting and trapping wild animals almost continuously, he killed thirty or more lions, suffered one severe mauling, and has survived to set down his experiences in a book of more than usual interest, adding as it does to our knowledge of the habits of Africa's great game His account, occupying the first third of the book, of his many adventures with the so called "King of Beasts" is, we think, one of the best and least coloured that has been written In reading some of his descriptions of hunts and exciting incidents, one may almost smell the pungent odour of the great night prowler after meat

Besides the author's own nearly fatal mishap, one or other of his men on various occasions was mauled by a lion or tossed by a buffalo, he is, therefore, in a position to say exactly what happens on these occasions Many authors describing the charge of a lion seem unable to avoid mention of great bounds and a mighty spring In reality, whatever the action at the commencement of the approach to a man or standing animal—whether creeping, galloping, or bounding according to circumstances, with head down and tail stiffened—

the final charge, in the present writer's experience, which agrees more or less with the author's, is a very quick and terrible rush, ending in the lion standing up with the great fore limbs widely extended, claws exposed, and mouth open. All happens in a moment, in a cloud of dust if in dry weather, the fearful right or left sideways blow with the huge paw, which does all the damage, coming almost too swiftly for the eye to follow.

The author, who made four expeditions in eastern equatorial regions before being interned for the duration of the War, also recounts his experiences with elephants in Uganda, but his knowledge of the greatest of beasts is not equal to what it is of the lion and the plains fauna, and, moreover, in this section he suffers apparently at the hands of his interpreter, the book being a translation from the Hungarian. His chapters, which are profusely illustrated with his own photographs dealing with most of the bush fauna and the birds, are very good reading. His final chapter contains useful directions on hunting equipment and the treatment of trophies.

The author's main interests throughout have been apparently the capturing and rearing of young animals, at which he seems to have become an expert. The majority of his antelopes were caught by driving the herds into loop nets, hung in eight or ten parallel rows, the young animals being afterwards turned loose in paddocks and fed, if very young, on milk from bottles fitted with rubber suckers. When tame enough, they were allowed out to graze with zebu cows herded in the same paddock and from which they never attempted to stray. In this way he was eventually able to drive a mixed herd of cows, antelopes and other animals, and ostriches down to the Victoria Nyanza or to the coast for shipment.

Life and Mechanism.

The Sceptical Biologist (Ten Essays). By Joseph Needham. Pp. v+288. (London: Chatto and Windus, 1929.) 7*s*. 6*d*. net.

OF these ten essays, seven deal with different aspects of a single topic, the character of the biological sciences and their status among the other sciences. Arising out of this question the relations between science and philosophy and other human activities are considered. Dr. Needham writes in a gay and even frivolous manner, but the subjects he deals with are serious and what he has to say is important. He does not claim that his main thesis is new, but he might justly claim that it has never been better stated.

The gist of the matter may be put in a few sentences. "The biologist is not committed to any opinion as to what his animals are in themselves, but he is committed to the opinion that the scientific method is one way of describing them, and that it is best to apply that method in its fullest rigour if it is to be applied at all" (p. 253). "The mechanistic conception of living organisms is necessitated by the fact that science is, above all, a system of measurement. What can be weighed or made measurable is susceptible of scientific treatment; elements of experience which cannot be so discussed are left on one side until they can" (p. 136). "The neo-mechanistic position, therefore, at one and the same time asserting the universal dominion of the mechanical sort of explanation over all nature, living and non-living, and admitting the inadequate nature of this sort of explanation as a full account of the world, resembles the old mechanisticism in maintaining the heuristic need for the machine, and differs from it in seeing nothing solely ultimate about the machine. It thus recognises itself as the way the scientific mind goes to work, and not the manner of thinking in philosophy, theology, and art" (p. 204). Everybody, in fact, who works in a laboratory has to be a mechanist while he is at work. Outside he may think what he likes. The mechanistic theory is like army discipline—necessary for the soldier on duty but intolerable otherwise.

While each individual essay can be unreservedly recommended, read together they do not make a good book. They resemble too much having to eat a succession of teas instead of a dinner.

The three other essays in the book are of a biographical character, but are not unconnected with the main theme of the others. One is on a forgotten biological essay by Coleridge; one on de la Mettrie, the author of "Man a Machine"; the third on the seventeenth century trials for witchcraft and Harvey's connexion with them. Unfortunately, it appears that Harvey never divulged his views on witchcraft, but the nature of his evidence at the trials combined with this very reticence seems to leave a presumption that he was sceptical. The essay is a very interesting little historical sketch.

The author displays a disconcertingly wide knowledge of scientific and philosophical literature and has a happy knack of quotation from unexpected sources. For this reason it is specially disappointing to find the bibliography incomplete. A. D. R.

Ethnography

The Corridors of Time By Harold Peake and Herbert John Fleure Vol 5 *The Steppe and the Sown* Pp 160 Vol 6 *The Way of the Sea* Pp viii + 168 (Oxford Clarendon Press, London Oxford University Press, 1929) 5s net each

IN these two volumes the authors of the "Corridors of Time" pass definitely to that phase of archaeological studies in which the comparative method on broad lines must at the very least take equal place with the intensive study of local conditions

Each of these two volumes has, in a sense, a dramatic unity and a central theme, better expressed perhaps in the title of the first than the second In "The Steppe and the Sown" the nomads of the plains of southern Russia, who, as it has been suggested, may have been the earliest Aryans, made more mobile by the domination of the horse, overrun and conquer the agricultural peoples, settling as overlords in eastern and central Europe, and ultimately reaching or affecting Mesopotamia, the Troad, the Balkans and Greece, Crete, and even Egypt, possibly giving rise to the Hittite Empire at a date later than that to which this volume extends "The Way of the Sea", which carries the story down to about 2000 B C, deals not so much with the migrations of peoples as the great movements of cultures, world wide and more or less lasting in their effects on indigenous civilisation, whether due to actual racial contact or to trade, not only by sea but also by land routes The range and character of the megalith, the spread of a knowledge of the use of metal, and the distribution of the 'beaker' are interpreted in terms of a widely extending continuity of contact

The authors have analysed the evidence with no little ingenuity in attacking some crucial difficulties In particular their view that the spread of the beaker must be regarded as a westward movement from eastern Europe seems more in accord with probabilities than that which regards it as an eastward spread from Spain Their treatment of the history of the great centres of civilisation, Mesopotamia, Babylon under Hammurabi, the beginnings of the Hittite Empire, Crete and the eastern Mediterranean and Egypt, is necessarily summary in character and can touch only on the evidence for the main trend of events

The Heroic Age of India a Comparative Study By Prof N K Sidhanta (The History of Civilization Series) Pp viii + 232 (London Kegan Paul and Co, Ltd, New York Alfred A Knopf, 1929) 12s 6d net

AN account of the heroic age of India fittingly finds a place in a series which aims at covering the history of civilisation Regarded integrally in its effect on the life of the peoples of India, the heroic age, as a phase of culture, must rank as an epoch of fundamental importance, but it has also to be recognised that in all probability it is, in mythical form, a record of one of a number of racial movements in world history which, having certain features in common, are mutually illuminative, and even in some cases may be interrelated Prof Sidhanta, throughout his study of the heroic age of India, points out again and again the similarities in the epic stories contained in the Mahabharata, the Puranas, and the Ramayana, and those of the Iliad and Odyssey, Beowulf, and the Serbian cycle of Marko, the hero of the battle of Kossovo

Study of the Indian epic cycle presents grave difficulties to the student who is not also an expert in the interpretation of Indian literature The religious and philosophic interest of a later age has remoulded these stories, thrusting the more purely heroic theme into the background Prof Sidhanta has done a valuable service in extracting from the poems the material which serves to throw light upon the chronology, the social system, and the religion enshrined in the tangled story of the heroes in the great struggle between Kauravas and Pandavas

As has been said, the author refers frequently to the other great heroic sagas in the world's history In seeking to explain the genesis of the heroic epic and the conditions of society which the heroic epic depicts, his method is literary rather than sociological Had he carried his analysis a little further and on sociological lines, it would have been apparent that the resemblances represent a racial reaction—the reaction of Nordic peoples—to analogous conditions

(1) *People of the Small Arrow* By J H Driberg Pp v + 338 (London George Routledge and Sons, Ltd, 1930) 10s 6d net
(2) *Jungle Gods* By Carl von Hoffman Edited by Eugene Löhrke Pp xxiv + 286 + 20 plates (London Constable and Co, Ltd, 1929) 10s net

(1) MR DRIBERG's "People of the Small Arrow" is a graphic description of characteristic events in the life of the Didinga of the hill country of the Sudan bordering upon Abyssinia The name here used is derived from the miniature arrow with which they bleed their cattle Mr Driberg was the first European to visit them, and a residence of some years among them has given him an intimate knowledge upon which he has been able to base these sketches of the normal course of their daily life Drought, warfare, cattle tending, agriculture, love, marriage, birth and death, are all described graphically as we would look to a novelist or descriptive writer to deal with the life of a community in a western civilisation Mr Driberg's special, and it may be said difficult, task has been to make intelligible the springs of action in custom and belief which determine the conduct of the individuals as individuals and as members of the social organism

(2) In "Jungle Gods", Capt v Hoffman is

dealing with a people still primitive in idea but no longer untouched by European culture These are the Lala, a people of north-eastern Rhodesia His method of treatment is comparable with that of Mr Driberg It is that of the graphic sketch of concrete incident and the record of ideas on specific points of belief and custom of the people themselves Here again it is possible to grasp the significance of magical ideas in their effect in action Particularly interesting is the way in which the author has brought out the psychology of the native attitude towards the missionary and other white activities

Taken together, the two books are of special interest in showing how graphic studies of this type may be made to supplement the scientific record of observations in the field They demonstrate how the beliefs, customs, and institutions described by the ethnographer function in the events and relations of everyday life

Le royaume d'Arda et son évangélisation au XVII^e siècle Par Prof Henri Labouret et Prof Paul Rivet (Université de Paris Travaux et mémoires de l'Institut d'Ethnologie, Tome 7) Pp iv + 63 + 20 planches (Paris Institut d'Ethnologie, 1929) 30 francs

THIS, the latest issue of the interesting series published by the Institut d'Ethnographie of Paris, deals with an intriguing problem in ethnography and geography It turns upon a small octavo book in the library of San Isidro in Madrid which came from the Imperial Jesuit College, and contains a vocabulary and exposition of the Christian doctrine in the 'Arda Language' It is dated 1658 The language was identified in 1858 by Ludewig as being that of an Indian tribe of the upper waters of the Amazon, and akin to the Yamio whom the Jesuits attempted to evangelise from 1727 to 1768 An examination of a photographic reproduction of the vocabulary, however, as well as the discrepancy in the date and the fact that it was the work of Capucins and not Jesuits, led the authors to doubt this attribution Certain words in the vocabulary were undoubtedly African They accordingly now identify it as the language of Allada on the Slave Coast, the cradle of the dynasty of Dahomey before it was made subject to the kingdom of Abomey in 1724 The title page of this interesting volume and the vocabulary are reproduced photographically with other interesting plates from early voyages

Psychology

The Morality of Punishment with some Suggestions for a General Theory of Ethics By Dr A C Ewing Pp xiv + 233 (London Kegan Paul and Co , Ltd , 1929) 10*s* 6*d* net

BOOKS upon the subject of punishment are usually written by humanitarians, cranks, or persons with some sort of a doctrinal axe to grind—theological or psychological Dr Ewing, however, contributes a thoroughly well thought-out and well informed dissertation, which will be read with profit by magistrates, schoolmasters, and clergymen, as well as with sustained delight by philosophers and students of ethics

Since Dr Rashdall wrote his well known chapter, "Punishment and Forgiveness", in his "Theory of Good and Evil", there has been nothing written in Great Britain of serious import on the subject, as Dr W D Ross points out in his foreword The author aims at reconciling the retributive and the deterrent theories of punishment in such a way as to do justice to the elements of value in both Such elements, indeed, do exist , and Dr Ewing, though repudiating the more savagely logical of retributive theories, has no difficulty in showing that the deterrent theory may be held and put into practice in such a way as to presuppose no visible moral point of view at all For the deterrent theory (logically applied) presupposes in the criminal only a capacity for feeling pain, not of any moral sense as such

Dr Ewing deals further with educative ideas of punishment, and also with the complementary theory of reward He adds a long chapter on the bearing of moral theory upon practice—that is, on the question how we are to decide in particular cases of conduct , a problem too much left by moral philosophers to the casuists whose inspiration has often been theological rather than humane Dr Ewing's work is of great value, and deserves careful study, not only by theorists but also by men of affairs It is commendably readable—not a common quality in treatises on ethics

The Foundations of Experimental Psychology By H Banister, Philip Bard, W B Cannon, W J Crozier, Alexander Forbes, Shepherd Ivory Franz, Frank N Freeman, Arnold Gesell, H Hartridge, Selig Hecht, James Quinter Holsopple, Walter S Hunter, Truman L Kelley, Carney Landis, K S Lashley, Mark A May, T H Morgan, John Paul Nafe, George H Parker, Rudolf Pintner, Eugene Shen, L T Troland, Clark Wissler Edited by Carl Murchison (The International University Series in Psychology) Pp x + 907 (Worcester, Mass Clark University Press , London Oxford University Press, 1929) 27*s* net

THE purpose of this large and comprehensive volume, issued from Clark University, one of the recognised homes of psychological research, is to indicate just where we stand at the present time in regard to the experimental method of inquiry in this field To review such a book in detail would be a rather hopeless task, since it consists of no fewer than twenty three independent studies of the subjects finally selected for treatment But many of our readers will be glad to have an indication of the contents of the volume

Chapters on heredity, the study of living organisms, and the mechanism of reaction, are followed by several chapters on the senses, two on emotion, and two on the psychology of learning Then follow studies on the individual in infancy and in school, the adult in the community, and the conflict and survival of cultures The last two chapters deal with statistical principles, of course with special

reference to their application to psychological problems Care has been taken to exclude problems which promise little reward for experimental inquiry, and to avoid saying over again what has been said many times before

The whole book may be regarded as an authoritative report on the present state of its subject, and we are promised that it shall be kept up to date by frequent revision The book represents a big enterprise worthily accomplished

Biology

Die Binnengewasser Einzeldarstellungen aus der Limnologie und ihren Nachbargebieten Unter Mitwirkung von Dr Einar Naumann und anderen Fachgenossen herausgegeben von Prof Dr August Thienemann Band 7 *Die Biologie der Moore* Von Dr Otto Harnisch Pp iv + 146 16 marks Band 8 *Der Hochgebirgsee der Alpen (Versuch einer limnologischen Charakteristik)* Von Dr Otto Pesta Pp xi + 156 + 8 Tafeln 17 50 gold marks (Stuttgart E Schweizerbart'sche Verlagsbuchhandlung (Erwin Nagele) G m b H , 1929)

FOLLOWING Dr Einar Naumann's excellent introduction to experimental fresh water plankton investigations in Vol 6 of the present work, we are now given treatises on the biology of the moor by Dr O Harnisch (Vol 7), and on the high mountain lakes of the Alps by Dr Otto Pesta (Vol 8) Both of these are highly interesting, and the student of fresh water biology will find much to help him, whichever region he wishes to investigate The plan of the volumes is similar, although naturally differing to a large extent in matter The first part treats of the geographical and geological features with the chemical constituents of the soil and water, and following this are descriptions of the fauna and flora of these distinctive regions

Dr Harnisch begins with certain necessary definitions and proceeds to describe the moor in all its aspects, including its development and history, the chemical and physical nature of the soil and the moorland waters—stream, lake, and bog, the trees and turf , finally, the plant and animal life The importance of *Sphagnum* to the Rhizopoda and other small creatures, always well known, is emphasised Special stress is laid on animal communities and their environment , the whole forming an excellent basis for further work

Dr Pesta, who has himself investigated many of the high Alpine lakes, gives a valuable account of them Most of these lakes have little or no vegetation round them, being situated chiefly between the mountains and surrounded by rocks and stones The hydrophysics, including colour and transparency, temperature and winds, are here of great importance The flora and fauna are mostly made up of cosmopolitan species with a small group of cold-water forms of restricted distribution The lists given include a large variety of plants and animals, and special problems arise out of these, such as the restriction of food in the winter and consequent hunger-forms, the presence of red coloration in many species, and other suggestive points

A Manual of External Parasites By Dr H E Ewing Pp xiv + 225 (London Baillière, Tindall and Cox, 1929) 20s net

THIS attractively printed manual, notwithstanding its title, is not a general book on ectoparasites, but a guide to the study of certain economically important groups Its author, Dr H E Ewing, is a well known member of the United States Bureau of Entomology, and in preparing this book he has been able to draw upon the extremely complete collections of the creatures he deals with that are contained in the National Museum at Washington The first five chapters are devoted respectively to mites, ticks, biting lice, sucking lice, and fleas Each of these sections contains keys to the families and genera, together with some considerations of the external anatomy, economy, and control measures, while representative species are shown in the illustrations At the end of each chapter is a list of the more important literature on the subject concerned the references are well chosen, and by no means confined to American writers The sixth and final chapter takes the form of an appendix containing descriptions of a number of new genera of ectoparasites The wisdom of this procedure is disputable, but, it may be added, the new genera described are included in the keys given in the foregoing sections

It is a matter of regret that the book is not larger, and its utility is limited in consequence Its chief value is that it provides a guide to the identification of the groups of ectoparasites dealt with, and we know of no other single work wherein there are to be found diagnostic keys of a similarly comprehensive character Museum workers, general entomologists, and veterinarians will find the book of real assistance in this respect From the general point of view, however, the information on structure and biology is not given in the detail which might reasonably be expected in a specialised book of this description, and the same applies to the accounts of control measures

Tabulæ Biologicæ Ed W Junk, Herausgegeben von C Oppenheimer und L Pincussen Supplement 1 (Band 5) *Botanik , Biologie der Algen , Bakteriologie , Hefen und Schimmel Pilze , Geschlechter Verteilung , Kern Plasma-Relations , Keimung , Wachstum , Allgemeine Physiologie , Assimilation , Periodizität , Experimentelle Ökologie* Pp vi + 821 (Berlin W Junk, 1929) 90 gold marks

THIS volume is supplementary to the original four It deals entirely with botanical data and is to be followed by a zoological volume A variety of matters relating to the biology of plants are tabulated Beginning with a list of all the species of algæ which have been cultured, many other facts which are amenable to tabulation concerning algal cultures are given In similar fashion, many facts concerning bacterial and fungal culture and media are tabulated Sections follow dealing with such subjects as sex in plants, germination, growth, and many other physiological topics in tabular form Another section is ecological, and the volume ends

with an appendix on enzymes and an index of all botanical references in the five volumes

References to the literature are given at the beginning of each table and at intervals in each section Much out of the way information is conveyed, which will be useful for reference But in some cases the tables would be more useful if the method of computing the results was given Thus in the table giving the nucleoplasmic ratio in embryonic organs, reference to the original paper would be necessary to determine how the volumes were computed Numerous graphs and four plates of figures of yeasts and moulds add to the value of a volume which should be of use both to morphologists and physiologists

Handbuch der biologischen Arbeitsmethoden Herausgegeben von Prof Dr Emil Abderhalden Lieferung 293 Abt 9 *Methoden der Erforschung der Leistungen des tierischen Organismus*, Teil 4, Heft 3 *Methoden der Erforschung bestimmter Funktionen bei einzelnen Tierarten Methoden und Technik der Nerven und Muskel physiologie bei wirbellosen Tieren* Von H J Jordan und P J van der Feen Pp 295-438 (Berlin und Wien Urban und Schwarzenberg, 1929) 8 gold marks

THE present sub section of this comprehensive undertaking will be found especially useful to workers in marine and in general physiology, as well as to those devoting themselves to the study of muscle and nerve phenomena General methods for the investigation of the tone of smooth muscle are described, as well as special details of technique for dealing with the representative types of invertebrates

What Darwin Really Said connected Extracts from the "Origin of Species" With an Introduction by Prof Julian Huxley (Routledge Introductions to Modern Knowledge No 8) Pp 80 (London George Routledge and Sons, Ltd, 1929) *6d* net

BY a judicious selection of extracts, Prof Huxley here presents the pith of Darwin's argument in support of the theory of natural selection, and in such a way that the layman in biology should have no difficulty either in grasping the essentials or in avoiding misconceptions The introduction, after showing the far reaching effect of the appearance of "The Origin of Species", contains a valuable discussion of the present position in the light of recent advances in biological knowledge, especially of Mendelism, while occasional footnotes direct attention to facts not known to Darwin A short bibliography of modern works relating to evolution, and a glossary, are included

Insect Pests and their Control in South Africa By Dr Charles K Brain Pp xii + 468 + viii (Cape Town Die Nasionale Pers Beperk, 1929) n p

IN view of the enormous losses occasioned by insect pests to the farmers of South Africa, we welcome this first attempt to provide them with a manual of the subject, with methods of control Dr Brain has brought to his task wide experience of his subject and has succeeded in producing a thoroughly sound, well-illustrated book which is both practical and scientifically accurate Within a compass of rather more than 460 pages, he discusses every pest of importance to the grower and stock raiser in South Africa, besides providing chapters on bee keeping, the relations of insects to human and animal diseases, and the general principles of control methods

English Wild Life By Eric Parker (The English Heritage Series) Pp xi + 180 (London, New York and Toronto Longmans, Green and Co, Ltd, 1929) *3s 6d* net

THAT the old order changeth is sadly true of the English countryside to those whose memories extend back to the last century It is thus good to have this record of what the wild life, both animal and plant, of England has meant and means to an all round naturalist and (*quondam*) sportsman who has a knowledge of the fauna and flora of moors and fields, woods and forests, foreshores, rivers, lakes, and mountain peaks May his pleasant little volume achieve some measure of preservation of our heritage before it is too late

Animals Looking at You By Paul Eipper Translated by Patrick Kirwan Pp vi + 187 + 32 plates (London and New York G P Putnam's Sons, 1929) *10s 6d* net

THIS remarkable work should be read by all zoologists and others interested in animal life It consists of what can best be described as a series of vivid verbal vignettes of incidents observed at Hagenbech's Stellingen zoo and elsewhere, and reveals much of the characters and temperaments of the great beasts and birds lodged in such establishments The thirty two magnificent photographic illustrations are as striking as the text itself The translation is very well done

Geography

Practical Hints to Scientific Travellers Edited by Prof H A Brouwer Vol 6 Pp v + 177 + 12 plates (The Hague Martinus Nijhoff, 1929) 5 guilders, *8s 6d*

THE sixth volume of this useful work, which now appears in a handier form than that of the first two volumes, treats of travel in Canada, the Argentine, Madagascar, tropical West Africa, and Oceania The articles vary in scope and treatment, as is obviously desirable in such diverse regions, but all are of an entirely practical character and should be very helpful to the scientific traveller No attempt is made to compete with volumes on various aspects of the countries or to furnish guides or handbooks Attention is concentrated on methods of travel, equipment, maps, food, and manners and customs that might affect the traveller The articles on the Argentine and West Africa are specially valuable, but all are useful and are written by men of practical experience

Greenland its Nature, Inhabitants and History By Th N Krabbe Translated from the Danish by Annie I Fausbøll Pp xvi + 129 + ix + 170 plates (Copenhagen Levin and Munksgarrd, London Oxford University Press, 1930) Paper, 33*s* net, cloth, 40*s* net

DR KRABBE spent the best part of twenty years as a physician in Greenland, during which time he visited most of the inhabited parts He is thus exceptionally well qualified to give a general account of the country, and particularly its inhabitants and their social conditions The book, which is printed in parallel columns in Danish and English, gives an admirable survey of the present state of the country and a sketch of its history It is of interest to note that the native population, under the care of the Danes, has increased from 10,000 in 1886 to more than 14,000 in 1926

The chief value of the volume, however, lies in its beautiful illustrations The numerous plates, which are provided with full descriptions, give a pictorial survey of Greenland on a scale that no other volume has attempted Many of the settlements are illustrated and the inhabitants receive special attention There are also fifty portraits of men who have been closely connected with the exploration of the country A full index and a good map add to the value of the volume

R N R B

Shipways to the Sea our Inland and Coastal Waterways By Ernest S Clowes Pp viii + 196 + 6 plates (Baltimore, Md Williams and Wilkins Co, London Baillière, Tindall and Cox, 1929) 20*s* net

THE author of this excellent survey of the waterways of the United States, and, in part, Canada, believes that the development of inland navigation is needed to solve many of the problems of cheap and efficient transport in America He develops this idea particularly in regard to the Mississippi basin and the interior plains of the United States The book, however, is not merely a piece of propaganda It embraces a historical, geographical, and economic survey of all the existing navigable rivers, canals, and lakes with a wealth of useful statistics Projects in hand and dreams of the future are also discussed The consideration of the proposed St Lawrence waterway for ocean going vessels is particularly valuable, because it appears to be free from the political bias which affects most discussions of this subject The volume contains a few maps, but they should have been clearer and more numerous

Open-Air Studies in Australia By Frederick Chapman Pp xx + 170 + 23 plates (London and Toronto J M Dent and Sons, Ltd, 1929) 10*s* 6*d* net

FOR full appreciation of this series of essays, personal acquaintance with the soil and scenery of Australia are necessary Nevertheless, the fundamental principles involved are of such universal application, and the allusions to features within the British Isles so frequent, that the reader who has a taste for open-air geology can be assured of interest in every chapter Incidentally, attention may be directed to the chapter "The Problem of the Coral Island", and the discussion of the results of the Funafuti Expedition Most of the illustrations are excellent, but a few are inconveniently small

Mathematics

Mathematics Preparatory to Statistics and Finance By George N Bauer Pp vii + 337 (New York The Macmillan Co, 1929) 8*s* 6*d* net

THE flood of elementary treatises dealing with statistics continues unabated, nearly all seem to be designed to aid students whose subjects are known or believed to require statistical methods, but who have already decided that they have neither the time nor the mathematical training to make themselves masters of the simple principles on which competent methods are founded The authors of these heroic stopgaps cannot fairly be blamed for this situation, so long as the large portion of the population which will need statistics in its practical business does not imbibe the fundamental ideas in their school mathematics, so long will university students require such courses as that under review The author shows a just perspective in saying (Preface, p v)

"This is not a book dealing with the subject of statistics, neither does it attempt to present the subject of the mathematics of finance It is a study of the simpler mathematical methods and principles that occur frequently in elementary courses in these subjects But many of the principles and methods included are applicable to the study of phenomena in other fields They have a wide range of usefulness"

The range of usefulness would certainly be greater if care had been taken to use common expressions in the sense which they bear in more advanced work On p 252 the 'standard error of an estimate' is spoken of as a test of 'goodness of fit' This it certainly is not The confusion which here lies in wait for those adventurous souls who ultimately win through to real tests of goodness of fit, is made worse by the fact that the standard error under discussion is not the standard error of the estimated regression, but a rather unsatisfactory estimate of the standard deviation from a regression formula

Within its own limits, however, the book makes the subject easy Explanations and examples are careful and abundant R A FISHER

Mathematical Tables and Formulas By Prof Percey F Smith and Prof William Raymond Longley Pp v + 66 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1929) 8*s* net

THIS collection of tables, mostly to four figures, contains logarithms, square and cubes, square and cube roots, reciprocals, Napierian logarithms and trigonometrical tables No differences are given In addition, there is a three figure radian table giving the six natural trigonometrical functions for arguments up to 3 20 This and the corresponding table of exponentials and hyperbolic functions are

definitely useful It is therefore a pity that they were not made more extensive instead of being cramped into four pages The formulæ, which occupy 25 pages, are not so well chosen There are no formulæ of spherical trigonometry, nor are the derivatives of hyperbolic functions and their inverses given Taylor's and Maclaurin's series should include a remainder term The table of integrals is, however, welcome The book is well bound and has a thumb-nail index, but the price is rather high

The Adjustment of Errors in Practical Science By R W M Gibbs Pp 112 (London Oxford University Press, 1929) 5s net

THIS little volume is "the result of an attempt to simplify and condense into a readable form the gist of the Theory of Errors" It deals with the elements of probability, normal curves of error, distribution of errors, lines of closest fit, correlation coefficients and ratios, observational errors, and so on The text is clearly and simply written, and is well illustrated by graphical diagrams The chief mathematical theorems upon which the theory of error depend are not given in the text, but are established separately in an appendix at the end Here the author has wisely aimed at giving clear and simple demonstrations in order that the mathematical treatment may be within the range of the non specialist In this he has in general succeeded , nevertheless, a fair amount of mathematical knowledge is necessary to appreciate fully some of the proofs, especially those dealing with the fundamental integrals

Lists of common symbols and special formulæ used throughout the book are given at the end, and an excellent system of cross-reference has been adopted

Elementary Differential Equations By Dr Thornton C Fry Pp x + 255 (London Macmillan and Co , Ltd , 1929) 10s 6d net

THIS volume is intended primarily for students of engineering, and is the outcome of 'out-of-hour' courses given at the Bell Telephone Laboratories It embraces the significance and origin of differential equations, linear equations of the first and higher orders, systems of linear equations and other equations of a higher order than the first The treatment is mainly practical, but a little elementary theory is included

The author recognises the danger of dealing solely with technical applications and has made a commendable attempt to develop sound mathematical principles so far as is possible in such a treatise Thus, there are sections devoted to brief elementary discussions on existence theorems, continuity, singular solutions, boundary conditions, essential conditions of convergence in series solutions, etc There is a good chapter on the geometrical interpretation of a first order equation, and the book is full of excellent examples bearing on a variety of important applications

The text is well arranged and printed, and the few necessary diagrams are very clearly drawn

Physics and Chemistry

(1) *Molecular Spectra and Molecular Structure a General Discussion held by the Faraday Society, September 1929* Pp iii + 611-954 (London The Faraday Society, 1929) 15s 6d net

(2) *Bandenspektra und ihre Bedeutung fur die Chemie* Von Prof Dr R Mecke (Fortschritte der Chemie, Physik und physikalischen Chemie, herausgegeben von Prof Dr A Eucken, Band 20, Heft 3) Pp iii + 87 (Berlin Gebruder Borntraeger, 1929) 7 60 gold marks

(1) THE Faraday Society's General Discussion on Molecular Spectra and Molecular Structure, held at Bristol on Sept 24–25, 1929, has already been reported in these columns (Oct 12, 1929) The full report, which has now been issued as a separate publication, is remarkable in that it contains not less than forty original papers, together with verbal and written contributions to the discussion It is, therefore, unsurpassed as a comprehensive survey of the important subject with which it deals, and has the special merit of being many months in advance of any volume that could be written by the most experienced author, since it discloses for the first time new facts and new opinions that can only gradually find their way into even the most up to date text books

(2) One of the most welcome visitors to the Bristol meeting was Prof Mecke, of Bonn, the joint author of a paper on "The Absorption Spectrum of Ammonia Gas in the Near Infra red" Prof Mecke is also the author of a monograph on "Band spectra and their Significance for Chemistry", published in a well known series of *Fortschritte*, or progress reports, on chemistry, physics, and physical chemistry A recent monograph of this series, on the valency number and its relation to the structure of the atom, was reviewed at length in these columns nearly a year ago (NATURE, April 13, 1929) Since the logical sequel to the study of line spectra of atoms is obviously that of the band spectra of molecules, those chemists who have read the former monograph in order to secure some knowledge of atomic physics will obviously be well advised to extend their studies to the latter monograph, which records the spectroscopic behaviour of chemical compounds and therefore presents a much wider field for the consideration of chemical problems In particular, those who wish to appreciate the technicalities of the Bristol report will find in Prof Mecke's monograph an excellent introduction to a very modern and somewhat difficult subject

Physikalisch-chemisches Praktikum Von Prof Dr K Fajans and Dr J Wüst Pp xvi + 217 (Leipzig Akademische Verlagsgesellschaft m b H , 1929) 13 50 gold marks

THE "Physikalisch-chemisches Praktikum" of Prof Fajans and Dr Wust had its origin in instructions for experiments in physical chemistry which were prepared in 1910 by Prof Bredig and his colleagues for use in his laboratory at Karlsruhe Ten years of continuous service in Munich resulted in so many modifications that finally a plan was

developed whereby the experience gained there was united with that of Prof Grimm at Würzburg and of Prof Schiebe in Erlangen and used to produce a book which would meet the requirements of the four laboratories mentioned above

The principal purpose of such a book is to lighten the burden which rests upon demonstrators who may now be required to cope with very large classes, as a result of the introduction of compulsory courses in practical physical chemistry Its value can only be tested adequately by use in the country of origin, and English teachers will probably find it necessary to base their courses on instruction sheets or laboratory text books in their own language, but they will find it of interest to compare notes with their German colleagues, and in some cases (for example, the experiments illustrating radio active transformations) they may find material for developments in directions not hitherto exploited in undergraduate courses The practical instructions are accompanied by theoretical sections, and references are given to German text books in which the points at issue can be studied more fully

Stereoscopic Photographs of Crystal Models Edited by Sir William and Prof W L Bragg in order to illustrate the results of X ray Crystallography Second series *The Silicates* (London Adam Hilger, Ltd, 1929) Set of 23 photographs complete in box with folding stereoscope, 24*s* 9*d*

THIS second series of stereoscopic photographs represents models of the structures of important members belonging to the silicate family The original models were built up from results based on X ray investigations, and they have been constructed with such simple materials that the student may be tempted to reproduce the simplest ones from the data printed on the back of each photograph Seeing that the atoms in these structures make up nearly the whole of the earth's crust, this simple presentation of the results of a difficult physical research will be of great interest in many fields

The key to each model is the regular grouping of the large oxygen atoms, the silicon and metal atoms being widely dispersed throughout the structure and adding, as it were, more complex harmonies to the central oxygen 'motif' Both the close packed and open structures of oxygen atoms are well represented These examples of complex co-ordination are made up of simple units, notably tetrahedral groups of oxygen atoms around silicon, and octahedral groups of oxygen atoms around aluminium The units are repeated rhythmically, often in chain or ring formation when they share one oxygen atom The variable co ordination number of aluminium is of particular interest to the chemist andalusite provides an example of this atom being situated between five oxygen atoms

It is to be hoped that photographs of models of the felspars, micas, and zeolites will form a nucleus for a third series To the mineralogist remains the formidable task of finding how closely these ideal models represent the structure of all the members of a mineral species, within which the chemical composition often varies widely F A B

Das Fermentproblem (zugleich Einführung in die Chemie der Lebenserscheinungen) Von Prof Dr Andor Fodor Zweite, völlig umgearbeitete Auflage Pp xi + 283 (Dresden und Leipzig Theodor Steinkopff, 1929) 20 gold marks

THE author's aim in the present edition of his book has been to prepare a concise treatise on fermentation phenomena, embodying the more recent discoveries, without attempting to treat the subject exhaustively The difficulties of dealing, within a limited compass, with a subject having so profuse a literature, are frankly admitted by Prof Fodor

The book is divided into five sections, each of which is subdivided A short account is given in the opening section of the history of fermentation The physiology of digestion is next dealt with, and a detailed account is given of the products resulting from the action of enzymes Some of the text in this part of the book is inclined to be one sided, thus, that concerned with starch hydrolysis is almost exclusively confined to the work of German chemists A useful summary is given of the enzymes of animal organs and of prophylactic ferments The section on assimilation and dissimilation is a long one, describing photosynthesis, respiration—aerobic and anaerobic—and setting forth the views of Bach and Chodat, Warburg, Wieland, and others Here also the final excretion products of animal metabolism are dealt with There is a section on the physical chemistry of enzymes, whilst the subject matter of the concluding section of the work is concerned with colloidal chemistry in its relation to the activity of enzymes A subject matter index is provided

Whilst regarding the book as a useful addition to the literature, after reading the sections the feeling can scarcely be avoided that it lacks that personal touch so desirable in a work intended for didactic purposes A R L

Analytical Processes a Physico Chemical Interpretation By T B Smith Pp viii + 373 (London Edward Arnold and Co, 1929) 12*s* 6*d* net

DR T B SMITH has written a book of a very unusual type, since it is neither a text book of analysis nor a text book of physical chemistry, but a review of the processes of analysis in the light of modern knowledge and of physico-chemical laws For this purpose he has considered a series of analytical operations, such as the precipitation of barium sulphate, lead sulphate, ferric hydroxide, and silver halides, the titration of chlorides against silver nitrate, of acids against alkalis, and of oxidising against reducing agents, and the methods of electro-analysis, and has brought to bear on them a wealth of physico chemical experience which may win the admiration even of a well read student of physical chemistry

The book also includes chapters dealing with the ignition of precipitates, analytical separations, super saturation and crystallisation, colloidal phenomena

and complex ions, each of which contains a satisfying review of current knowledge The author has, in fact, first become a keen student of the science (as distinct from the art) of analysis, and has then set himself the more difficult task of passing on to others the scientific equipment and critical skill which he has himself acquired The volume in which this has been done is a noteworthy production, and may be commended heartily to all those who are responsible for teaching analysis, as well as to those who may value it for the additional interest which it may give to analytical practice

Miscellany

The Evolution of Earth and Man By Lorande Loss Woodruff, George Howard Parker, Richard Swann Lull, Charles Schuchert, Harry Burr Ferris, Joseph Barrell, Albert Galloway Keller, George Grant MacCurdy, Ellsworth Huntington, James Rowland Angell, Edwin Grant Conklin, Wesley Roswell Coe Edited, with a Preface, by Prof George Alfred Baitsell Pp xv + 476 + 32 plates (New Haven, Conn Yale University Press, London Oxford University Press, 1929) 22*s* 6*d* net

THIS volume consists of a reprint of two volumes of elementary lectures, "The Evolution of the Earth and its Inhabitants" (1918), and "The Evolution of Man" (1922), delivered at Yale University, with the addition of a chapter entitled "Cultural Evolution" by Prof G G MacCurdy, and another on "The Mechanism of Evolution", by Prof W R Coe Most of the chapters are reprinted without any (or with only slight) alteration Hence the review that appeared in NATURE (June 2, 1923, p 735) still gives an accurate idea of the new impression, and the criticism of the titles of the individual lectures and of the whole volume is still relevant

The new chapters are summaries of well known evidence, which omit a good deal of modern research For example, the beginning of the Bronze Age is given (p 285) as 3000 B C, although it is now generally admitted that the alloy was not invented before 2500 (or perhaps even 2000) B C, and some time must be allowed for the building up and diffusion of the culture complex which in western Europe was called 'The Bronze Age' The beginning of the Neolithic Period is assigned to 12,000 B C, which is about nine or ten millennia too early

Nature Cosmic, Human and Divine By James Young Simpson (The Terry Lectures, Yale University, 1929) Pp ix + 157 (London Oxford University Press, 1929) 6*s* net

PROF J Y SIMPSON'S three Terry Lectures delivered at Yale last year will interest those students of science who are not indifferent to the speculative and religious bearings of their subject The first lecture summarises the results of recent astronomical and physical science The second lecture, which is anthropological, takes an optimistic view of human nature, accepting Elliot Smith's view that 'savagery' is not natural to man, and expressing the opinion that "human nature not merely can be, but is being changed", and (what seems too good to be true) that 'we stand on the threshold of an Age of Reason"

The final lecture essays to present us with some sort of a philosophic synthesis in terms of trends and tendencies "The association of mind with the energy at work in the world process is forced on us in contemplation of the sustained and broadly progressive character of the process as a whole, with its present *dénouement* in man" The Christian theologian will discover in this last chapter a point of view indistinguishable from the *Logos* doctrine of the Fourth Gospel, nor would Dante feel that his view of love as the motive power of the world had been neglected Prof Simpson may be congratulated on a very useful piece of work

The Scientific Examination of Pictures an Investigation of the Pigments used by the Dutch and Flemish Masters from the Brothers Van Eyck to the Middle of the 19th Century By Dr A Martin de Wild Translated from the Dutch by Dr L C Jackson Pp xv + 106 + 46 plates (London G Bell and Sons, Ltd, 1929) 15*s* net

DR DE WILD has made an examination of the pigments used in painting Dutch pictures from the fifteenth to the nineteenth century inclusive, by micro-chemical methods, thus enabling him to use tiny samples without injury to the pictures, and carrying on the work done by former chemists such as Raehlmann and Laurie The work, on the whole, confirms the conclusion formerly arrived at as to the pigments used at different periods in painting, but adds much detailed information on the pigments of the Dutch school during this period The beautiful photomicrographs of actual examples are well worth looking at

There are other chapters on the cleaning and preservation of pictures, the examination of them by means of X ray photographs, and by means of ultra violet light

The work is a solid and useful contribution to a subject of growing importance and should find a place both on the bookshelf of the chemist and the picture expert A P LAURIE

Isis or the Future of Oxford By W J K Diplock (To day and To morrow Series) Pp 95 (London Kegan Paul and Co, Ltd, New York E P Dutton and Co, 1929) 2*s* 6*d* net

DISSATISFIED with Mr Julian Hall's "Alma Mater", recently published in the same series, on the future of the two older universities of England, Mr Diplock has produced a sparkling and thoughtful essay on Oxford as it appeared to him during the past five years, when spending laborious days in chemical laboratories, and nights in discussing 'life' and topics of wider intellectual interest with non-scientific friends He not unnaturally prefers the Oxford of his leisure hours, and points out how the 'old academic tradition' may be in danger, if women become too numerous, or if benefactors

prove too commercially-minded, or if 'job hunters' increase At the same time, he notes the absence of heads of colleges who have had a scientific training, whereas Cambridge has often benefited by their ability We hope that Mr Diplock will enlarge further on his theme

Are we Civilized? Human Culture in Perspective By Robert H Lowie Pp xiii + 306 (London George Routledge and Sons, Ltd, 1929) *12s 6d* net

In this amusing and witty book, Prof Lowie has made a survey of human culture with the view of analysing the permanent and impermanent elements in the line of progress His thesis is that man, like the chimpanzee, must fight against the forces of destruction, but he has forged ahead of the ape by passing on his experience to his descendants of the next generation Prof Lowie aims at showing that in so doing he has passed on dross as well as gold In his time and space survey, he shows that identity in difference leads to the conclusion that we our selves, however much we may differ from our ancestors and the so called 'lower races', retain much in our own make up, 'inherited' in the looser sense, which justifies the interrogative which forms the title of his book Prof Lowie holds no brief for the popular theory of Nordic superiority, because, as he says, he does not recognise that a Nordic race exists to day Like everything he writes, the book is stimulating Though scientific in method and outlook, it is written in a style which avoids technicalities and will appeal to the least instructed of readers

Exhibition in 1872 and was labelled prophetically "A Young Engineer" The headmaster of his first school, Cargilfield, Edinburgh, encouraged his mechanical tastes When at this school he gave exhibitions with a magic lantern and became skilled in taking photographs In 1877 he took a good photograph of Prof T H Huxley which, with other portraits, is included in a book entitled "Autobiographical and other Writings", which was in the press when he died In 1878 he was sent to Fettes College, but as he hated games he found the school life very uncongenial In his opinion the way Latin and Greek were taught in public schools, especially the unnecessary stress laid on grammar, took away all the romance from the wonderful stories of Greece and Rome He also considered that compulsory games had a tendency to damp out any originality a boy might possess He, however, enjoyed the work in the carpenter's shop at Fettes

In 1879, after reading the description of the working of a telephone given by Prof Dolbear, Campbell Swinton constructed a pair of telephones which functioned excellently As the telephone had only been invented some two years previously, this would have been a good piece of work for a scientific worker, for a boy of fifteen it was admirable His house master, thinking that his scientific absorption interfered with his classical studies, made him send the telephones home

In the easter of 1881, Alan was sent at his own request to Havre, where he had lessons in mathematics and French, but he seems to have spent much of his time in taking snap photographs of ships and fishing boats He also visited the lighthouse on several occasions and studied how the electric arc was fed by a de Meritens dynamo which had permanent steel magnets He was puzzled by the fact that the current seemed to have no effect on a little compass needle brought near it, the reason being that it was alternating current

Campbell Swinton was a great believer in self education The passing of advanced examinations he regarded as pure waste of time He attributed his success to cultivating scientific friends and to attending lectures at institutions like the Royal Institution and the Royal Society of Arts

In 1881, Campbell Swinton visited the Paris Exhibition and was most impressed by the wonderful electrical inventions he saw In 1882 he was apprenticed to Lord Armstrong in the works at Elswick During this period he fitted a Chilian battleship with electric gun firing control which enabled any number of guns to be fired simultaneously In 1887 he left Elswick and set up in London as an electrical contractor and consulting engineer He installed the electric light in many town and country mansions

Early in January 1896, after reading an account in the morning paper of Prof W C Rontgen's discovery of X-rays, Swinton was successful in obtaining a shadow photograph by means of a Crookes tube which he happened to possess A few days later he obtained a shadow photograph of the bones in his own hand The present writer remembers him showing this at the Camera Club, which was then in Charing Cross Road This was the first photograph produced by Rontgen rays in Great Britain It was reproduced in NATURE of Jan 23, 1896 On Feb 4, 1898, he showed many interesting experiments with cathode and X rays at the Royal Institution In conjunction with Sir Charles Parsons, he converted diamond into coke by heating it in a vacuum by cathode rays As the diamond became carbonised, it split up and frothed and became much larger in size The temperature at which this conversion took place was 1890° C

In 1904, Campbell Swinton gave up contracting work and became exclusively a consulting engineer He was specially interested in radio work When the Marchese Marconi first came to England he called on Swinton, who introduced him to Sir William Preece and rapid developments in radio telegraphy soon ensued When in Copenhagen in 1910, Swinton first heard articulate speech by radio when listening to tests with the Poulsen system He was associated with the development of the Parsons turbine and was a director of the Parsons Marine Steam Turbine Co, Ltd He went out on many of the trials of the pioneer turbine boat, the *Turbinia*, which created a sensation at the Naval Review in 1897 by going at the record speed (at that time) of 33½ knots Swinton was one of the pioneers of motoring in England

Campbell Swinton was associated with many electrical works and supply stations He was a director of Crompton, Parkinson, Ltd, and of W T Henley's Telegraph Works, Ltd In 1911 he was president of the Rontgen Society and in 1913 of the Radio Society For several years he was chairman of the council of the Royal Society of Arts In 1915 he was elected a fellow of the Royal Society and twice served on the council In 1926 he presented the Royal Society with £1000 to form the nucleus of a general purposes fund He undertook to defray the costs of the charter which was recently granted to the British Association He had been a member of the general board and of the executive committee of the National Physical Laboratory He was well known at the Athenæum Club, of which he had been a member for nearly thirty years, he was unmarried

Campbell Swinton was a member of the three professional engineering institutions—the Civils, the Mechanicals, and the Electricals He had been a vice president of the Electricals for four years and had served energetically on many committees In his home in Chester Square he was most hospitable, and enjoyed showing to his guests the photographs he had taken of many eminent scientific workers and demonstrating the latest developments in radio communication He will be missed by many, and especially by his old assistants, with whom he maintained a warm friendship

A R

News and Views.

Nearly everyone agrees that radio telephone services with the Dominions and distant foreign countries should be opened up whenever it is economically practical Last August, Imperial and International Communications, Ltd, wrote to the present Postmaster-General, Mr Lees Smith, inviting the Government to work its radio telephone services through the company's stations, beginning with four services to Canada, Australia, South Africa, and India Whilst negotiations were going forward and before the special committee had reported, statements appeared in the Press giving an *ex parte* presentation of the case coupled with a series of charges against the Post Office Mr Lees Smith very properly did not reply until the committee had reported The evidence showed that both the Marconi system and the Post Office Rugby system are capable of providing long-distance services to the Dominions and foreign countries Owing to its invaluable pioneer work on short-wave systems, our sympathies are with the company, but we think that the Government has acted rightly in putting the matter into the hands of the Post Office There is no intention of duplicating the Marconi stations, and there are many advantages in concentrating the plant and buildings at Rugby To work the four services to India and the Dominions through stations belonging to Imperial and International Communications, Ltd, would require 4190 miles of high grade telephone circuits connected with London as compared with 786 miles to connect with the P O stations at Baldock and Rugby In South Africa, also, it would be more economical to erect a station at Johannesburg than to connect with the Company's terminal beam station at Cape Town We do not see that there was any necessity to make a comparative experimental test between the systems before coming to a decision

Scientific and industrial research in the British Empire was the subject of a paper read by Dr A W Hill, director of the Royal Botanic Gardens, Kew, before the Dominions and Colonies section of the Royal Society of Arts on Feb 25 The rapid growth of research in all branches of biological science during the last few years throughout the Dominions and Colonies has created a demand for trained men which it is at present very difficult to meet Dr Hill referred to developments in the West Indies and West Africa In the former, the Imperial College of Tropical Agriculture has been evolved and is recognised as a research station for the study of the many pressing problems which confront tropical agriculture It is also a training centre for agricultural officers for the various agricultural departments throughout the Colonial Empire Botanic stations have been established in West Africa to serve generally for the growth of indigenous trees and plants of marketable value as demonstrations to the natives, for the introduction and propagation of alien plants of economic and commercial importance, and as practical agricultural schools for training the natives The stations have expanded into agricultural departments, that in Nigeria having, in addition to the director, a staff of forty-four scientific officers besides native assistants The research station at Amani, Tanganyika Territory, which was founded by the Germans, has been reorganised as a station for the East African Colonies

Dr Hill emphasised the importance of an intensive taxonomic and ecologic study of the vegetation of the overseas portion of the British Empire, and referred to the important services of Kew, especially in the issue of a series of Colonial floras, and indicated similar works in preparation or projected which would deal in detail with smaller areas The work in progress and in contemplation in connexion with scientific research on the vegetation of the Empire calls for a great increase in the numbers of well-trained botanists both at home and overseas, especially in the domains of taxonomy and ecology, and for the investigation of plants yielding economic products Workers in the field of genetics are also required for the study of staple products, to produce and select true-breeding types which will give a maximum yield There are also the many problems in plant pathology, so closely linked with progress or failure in intensive agriculture Have we the scientific staffs properly equipped throughout the Empire for the great tasks that confront us? In conclusion, Dr Hill quoted from the Norman Lockyer lecture delivered by Sir Walter Morley Fletcher before the British Science Guild in November last and stated that his remarks on the inadequate remuneration and status of those engaged in medical research are equally true with regard to botany and agriculture

The Young Kikuyu movement is again a cause of grave anxiety to the Kenya Government Further, it is stated, attempts are being made to spread unrest to the peaceful Akamba The causes of the present disquiet are reviewed in an article which appeared in the *Times* of Feb 27 In that article the gravity of the situation is by no means exaggerated The Young Kikuyu movement, which has now taken on the form and title of a 'Kikuyu Central Association', is composed largely of younger members of the people who are impatient of the control of the elders and have thrown off tribal restraints In the present situation, however, it is probable that to some considerable extent they will have the support of the elders When it is remembered that the Kikuyu number some 800,000, it is clear that the situation requires statesmanlike handling The chief point now at issue is not one on which conflict is directly with the Government, but the danger is that the Government may be implicated The question is one of missionary control and the conditions on which converts will be admitted to, or allowed to remain in, the Christian churches For some time past, attempts have been made to abolish the practice of clitoridectomy on young girls on the ground that it is a cause of disease and of infant mortality This operation is an essential part of the female initiation ceremonies The missions have made it a rule that no convert or candidate for admission to their churches shall take part in or be a party to female initiation.

THE real bearing of this regulation on the situation in Kenya only becomes apparent when it is realised that without undergoing the operation as a part of the initiatory rite no girl can take her place among the marriageable women of the tribe She ceases to be a valuable asset, no man will seek her in marriage, and the bride-price she would have earned is lost to her family group Hence the missionary prohibition strikes at the roots of tribal organisation and the rights of property and the family The question of the so-called 'obscene' dances and scurrilous songs about persons in authority which the chiefs are trying to suppress on behalf of the Government stand on a different footing The missions are under a serious responsibility in having brought into the political field an issue of such gravity to the whole Kikuyu people However desirable the elimination of the initiatory operation may be, it is not one with which the Government should interfere, at any rate at the present stage of Kikuyu development Would it ever be considered tolerable that any civilised government should interfere with, or place a ban upon, any one participating in the Jewish rite of circumcision ?

THE Archbishop of York scarcely showed Christian spirit in his reference to science students in the newer universities, when speaking on behalf of the Student Christian Movement at York on Feb 27 On account of the large number of students taking science subjects in these universities, the Archbishop is reported in the *Yorkshire Post* to have said, "We are shortly going to be confronted with the peril of a purely scientific education", and he regarded the Student Christian Movement as "the main corrective we have at present to cope with the worst tendency of our contemporary education" He also suggested that students of science as a body are irreligious and without any knowledge of social values, so that "when they come to talk about anything that cannot be measured, anything of civic interest, they talk like children in the nursery" It would be interesting to know the evidence upon which Dr Temple bases his perverted conceptions of science students and of the influence of scientific teaching We have no hesitation in saying that a truly spiritual frame of mind is just as often found among students of science in our universities as it is among arts students, and we can assert with the same confidence that nothing in the teaching of science subverts the highest religious thought or noblest social endeavour The attitude of a student towards these things is largely determined by the influences of his home and school before he proceeds to a university, and the main subjects taken up by him have little to do with it We suggest indeed that, in these days, a purely literary education is a greater peril to progressive life than is the "purely scientific education" which the Archbishop of York regards so fearfully After all, a student of science is not necessarily limited in his reading to technical treatises or in his interests to the laboratory He often takes an active part in spiritual and social movements in spite of what Dr Temple says, and he might reasonably ask for just regard to be shown towards his scientific studies as factors even in a religious life

AT the annual general meeting of the Institution of Mechanical Engineers on Feb 21, the report for 1929 was presented From this it appears that there has been an increase of 279 in the total number of members, which now is 10,745, this being inclusive of 1401 students and 1238 graduates Eighteen papers were presented during the year, and reference is made in the report to the work done by the provincial branches The value of the national certificates granted on the examinations held throughout Great Britain was shown by the increased appreciation of them both by their holders and by employers During the year more than 1200 certificates were issued The council has conferred honorary life memberships upon Dr H S Hele Shaw, who has been a member of the Institution since 1879, and served as president in 1922, and upon Baron Shiba of Tokyo, who has long been associated with the mechanical engineering industry in Japan and took a leading part in the recent World Engineering Congress at Tokyo Mr Loughnan St L Pendred was installed as president of the Institution in succession to Dr D Adamson Born in 1870, Mr Pendred was educated at Finsbury Technical College, and gained practical engineering experience not only in important British works, but also in others in Belgium and France, and in 1896 joined the staff of *The Engineer*, of which his father, Vaughan Pendred (1836–1912), had been editor since 1865 On his father's retirement, in 1905, Mr Pendred succeeded to the editorship, which has thus been held in the same family for no less than sixty five years

AT the same meeting of the Institution of Mechanical Engineers, the sixth report of the Steam nozzles Research Committee was read and discussed The Committee, which was formed in 1914, has for its objects the measurement of the efficiency of nozzles of practical form, and the investigation of the manner in which the efficiency is affected by changes in the shape of the nozzle and by the pressure, velocity, and temperature of the steam passing through it Though delay was occasioned by the War, the work has been carried on continuously since 1921, and the results have been applied with good effect to the design of turbines The sixth report is the final one and is virtually a clearing up of all that has been done, which includes the construction of a testing apparatus for any usual form of steam nozzle with steam flowing at speeds from 300 ft to 2000 ft per second, the measurement of efflux angles, tests of built up impulse nozzles, tests of reaction nozzles, and determinations of the effects of roughness and other points connected with nozzle design The investigations have been carried out in conjunction with the British Electrical and Allied Industries Research Association The results which have been obtained should be of great value to turbine builders

IN a paper on "Pioneer Ships of the Atlantic Ferry", read on Feb 19 to the Newcomen Society by Engr Capt E C Smith, many hitherto unpublished particulars were given of the vessels by which trans Atlantic steam navigation was inaugurated By 1838,

three companies had been formed for the purpose of establishing regular communication between England and America by steam, and in that year the *Sirius*, *Great Western*, *Royal William*, and the *Liverpool* were placed on the route To these vessels were added in 1839 and 1840 the *British Queen* and the *President*, which, like the others, ran to New York, and then came the formation of the Cunard Company and the dispatch of the *Britannia* and her sister ships to Halifax and Boston Of all these vessels, the *Great Western* was the most remarkable, and she continued to run until 1846, making 74 passages in all Tables were given of the voyages of each ship, with particulars of the ships and their machinery and of the relative times taken by the sailing liners and the steamships The *Sirius* and *Royal William* were not built for work in the Atlantic and were soon withdrawn During 1839, however, the *Great Western*, *Liverpool*, and *British Queen* made regular passages and, whereas the outward voyages by sail averaged 33 days, the average time taken by the three steam vessels was only 17 days Of the four pioneer ships built for trans Atlantic work, the *Liverpool* was sold to the P and O Co , the *British Queen* to Belgian owners, the *Great Western* to the West Indian Royal Mail Co , and the *President* in 1841 foundered at sea without anything being heard of her

THE February issue of *Scribner's Magazine* contains the address entitled "Alleged Sins of Science", delivered by Dr Robert A Millikan at the recent meeting at Des Moines of the American Association for the Advancement of Science The address rebuts the charges brought against science by Mr Raymond Fosdick in a recent volume, "The Old Savage in the New Civilisation" "Have we spiritual assets enough to counterbalance the new forces ?" and "Can the old savage be trusted with the new civilisation which he has created ?" are the challenging questions to which Dr Millikan replies Speaking of the sinister possibilities latent in molecular physics envisaged by Prof F Soddy, whereby the equivalent of 150 tons of dynamite could be carried, like a flask of contraband whisky, in the hip pocket of every American citizen, Dr Millikan is able to reassure us that subatomic energy is not likely to be available in dangerous quantities Science, he points out, concerns itself with fertilisers quite as much as with explosives, though as "a horror makes better news than a wheat crop", we hear more about the latter than the former Indeed, science is likely to be effective in abolishing war by doing away with its primary cause, which is a lack of balance between population and food supply "That, in the last analysis, is mankind's greatest problem" Dr Millikan is prepared to admit that in some respects the rapid process of scientific knowledge has created an undesirable mentality in the public Novelties have fostered an omnivorous and quite undiscriminating appetite for what is new, which displays itself in literature in the works of what Mr Stuart Sherman has aptly called the emetic school, and in the experimentalist school in ethics But Dr Millikan has made out a good case for the comparative beneficence of science.

THE Imperial Geophysical Experimental Survey, which has been operating in Australia for nearly two years, under an arrangement between the Empire Marketing Board and the Commonwealth Government, is now finishing its work The leaders of the various sections are at present engaged in Melbourne upon the drafting of their reports, under the direction of Mr A Broughton Edge, leader of the Survey, and Prof T H Laby Electric, gravimetric, seismic, and magnetic methods have been adopted, the object being to test their applicability under Australian field conditions For the most part British instruments have been used The areas examined include Anembo, Captain's Flat, Leadville, and Gulgong in New South Wales , Cooper's Creek, the Mallee, Laverton, Gellibrand dale and Lakes Entrance in Victoria , Chillagoe in Queensland , Zeehan and Renison Bell in Tasmania , Moonta Wallaroo and Port Lincoln in South Australia , and Northampton in Western Australia The governments in all the States have undertaken to test promising indications by drilling and, though there have been delays in certain areas, it is hoped that the results will be available in time for inclusion in the final report

THE areas in Australia selected for the geophysical survey provided opportunity for testing geophysical methods for the location of sulphide ores (lead, copper, and iron), gold deep leads, brown coal, stanniferous pyrrhotites, graphite, and also water horizons (in the Mallee) The results on the whole are decidedly interesting, and are regarded in Australia as thoroughly justifying the survey One outstanding point of interest is the complication introduced by the saline waters which are present at comparatively shallow depths over large portions of the continent In places, electrical methods are of very little value for this reason but the members of the survey have been successful in effecting useful modifications of apparatus by means of which it has been possible to gain results over areas where at first there seemed little chance of success The report will be in two portions, one dealing with the objectives and field results and the other giving much more detailed accounts of theory, apparatus, and field procedure A draft will be submitted to the British Geophysical Committee and the final report will probably be printed and published in England

SIR HUBERT WILKINS, on his return to Montevideo from Deception Island, sent an account to the *Times* of his flight to the south early in February, when he searched in vain for a suitable starting point for a flight to the Ross Sea Travelling south west in the *William Scoresby*, lent by the Falkland Islands government, he met the pack ice about thirty miles south of Peter Island Weather conditions were bad, but the seaplane was launched on Feb 1 in about lat 70° S , long 100° W (the figure of long 145° given in the report is clearly a mistake) The weather became worse , visibility was very bad In lat 71° S it was noted that the edge of the pack spread westward In a position which Sir Hubert believes was about lat 73° S , long 101° W , he saw no indication of land or

barrier ice, but a number of large bergs, and much pack ice From there the flight was directed back to the ship, which then set a course for Deception Island, sounding and trawling on the way These observations will amplify the work done by the *Belgica* in those seas in 1898–99 on a course slightly farther in the north Sir Hubert Wilkins believes that a meteorological station might be established in about long 100° W by seaplane, but it would be difficult He does not think a sea going ship could hope to reach land and land ice in that area, but suggests that a submarine might well be utilised

THE occurrence of a spell of summer like warmth over the eastern parts of the United States was reported on Feb 25 last in the daily Press Among the more notable maximum temperatures quoted were one of nearly 84° on Feb 24 at Washington, and of 75° at New York on the same day The weather charts for the northern hemisphere published daily by the Meteorological Office, based on observations made at 8 P M (American time) at the official stations of the U S Weather Bureau, confirmed the occurrence of very exceptional conditions, and an examination of successive charts give some idea as to their immediate cause Over the temperate latitudes generally, the slope of temperature from south to north is sufficiently steep to make the occurrence of unseasonable warmth at a time of the year when the direct heating by the sun is small merely a matter of transport of air from low to relatively high latitudes This must happen when the run of the isobars is from south to north over a wide area for several days in succession, as was the case over the eastern part of the United States for several days before Feb 25, for the general drift of the wind in the lower layers of the atmosphere is in accordance with the direction of the isobars

A MAXIMUM of 75° has not occurred at New York in February during at least forty eight years, the previous highest having been 69° The exceptional feature on the weather charts during this 'heat wave' in the United States was the length of the trough of low pressure that provided the southerly winds, there are not sufficient observations to show whether it extended as far as the equator, but the northern shores of the Gulf of Mexico experienced such winds for several days, with a rising temperature that yielded at least one 8 P M reading so high as 80°, and this is scarcely likely to have happened unless the winds extended a long way farther south In the opposite direction, the same air stream appears to have continued without a break to the neighbourhood of southern Greenland and Iceland, where it was deflected into the south westerly wind characteristic of those regions

THE Air Ministry announces that in consequence of the rapid development of the international organisation for the collection of weather reports, it has been possible for some months past to prepare each day in the Meteorological Office, London, a chart showing the weather for the greater part of the earth's surface north of latitude 40° N At first, copies of this chart were prepared by a cyclostyle process for use in the Meteorological Office, but demands for copies became so large that it was necessary to arrange for them to be lithographed, this chart has, however, never been made generally available to the public The importance of this chart to everyone interested in the weather is so great that it has been decided to issue it daily as part of the *Daily Weather Report* This has necessitated a rearrangement of the matter printed in the *Report* and an increase in the size of the sheet, which now becomes 13 in × 12½ in When the new *Report* is opened out, the left hand half shows a weather chart of the British Isles with forecasts, general inference and further outlook This page also contains the data from health resort stations The right hand half shows the new chart of the northern hemisphere with the north pole slightly displaced from the centre of the sheet, thus allowing North America, Europe, North Africa, and northern Asia to be included The two back pages contain the complete set of observations made at the telegraphic reporting stations in the British Isles four times each day, namely, 1 A M, 7 A M, 1 P M, and 6 P M, with a large amount of miscellaneous information and full explanation of the symbols used The opportunity has been taken of improving the general appearance of the *Report*, the land areas now being printed in buff colour, and the weather information overprinted in black The new *Daily Weather Report* came into use on Mar 1, and may be obtained from the Meteorological Office, Air Ministry, Kingsway, London, the price being 1½*d* for single copies, or 6*s* 6*d* a quarter, or 25*s* a year, post free

PROF G I TAYLOR's Friday evening discourse at the Royal Institution on Feb 28 took the form of an account of his tour in the East Indies after attending, as a British delegate, the Pacific Science Congress held in Java last year During and after the Congress the Government of the Netherlands Indies provided every possible kind of hospitality and opportunity for seeing their countries The journeys described were illustrated by means of films taken by a small cinema camera The first film showed a visit which some members of the congress paid to Krakatau In 1883 this island was the scene of the greatest volcanic disturbance ever recorded Extensive researches have shown that all animal and vegetable life was then completely destroyed, and the successive stages of their gradual reappearance have been of great interest to botanists and zoologists At the present time, quite large trees have established themselves and the film showed a stage in which the *Casuarina* trees are already being suffocated by huge creepers A visit to a small island called Suak Krakatau which appeared mostly in 1928 was of interest, because a few weeks after the film was taken the island disappeared Two further films illustrated a journey in Borneo by river and jungle from Dutch territory to Sarawak This journey was undertaken by Prof Taylor and his wife, by the kind and efficient help of H H the Rajah of Sarawak and of Dutch officials The film showed the journey up the Kapoewas River, the trek through the jungle with a party of Dyaks, and an

impromptu dance by one of them at a resting-place in the jungle The end of the film showed the descent down the Lupar River in a long dug out canoe paddled by Dyak boatmen and a visit to a Dyak kampong

Members and friends of the Manchester Microscopical Society, which was founded in 1880, met for a jubilee reunion on Feb 20 at the rooms of the Literary and Philosophical Society An address by Prof S J Hickson, who was unavoidably prevented through illness from attending, was read by the president, Dr John Walton, lecturer in botany at the University of Manchester Prof Hickson chose for his subject "Biology and Beauty", and developed the idea that, in opposition to the older classical view of education, there is in the study of biology, and especially in the intricacies of the technique required, a distinct cultural and æsthetic value which has a refining influence and is a strong incentive to further work and research, while the utility of biology is every day becoming more apparent Of four living past presidents only one, Prof Weiss, was able to be present The Society, the largest of its kind outside London, can look back with satisfaction on its unbroken half century's work, from its beginning it has counted in its ranks those who might find themselves in everyday life classified as employers and employed, but who meet on terms of equality united by a common interest in biology and microscopical science The Society includes among its members professional scientific workers as well as those to whom science affords a recreation after their usual daily occupations It has also had strong support from members of the University, in the laboratories of which many of its exhibitions have been held In these days, with so many applications of the microscope in industry, the Manchester Society can look forward with confidence to a new era of usefulness

The Kampala correspondent of the *Times* announced recently (Feb 20) that a gorilla sanctuary has been proclaimed in the south west corner of Uganda in the neighbourhood of the Sabinio mountain and the Belgian Congo border This rounds off the gorilla territory, of which a portion had already been proclaimed a sanctuary by the Belgian Government, and, if adequately watched, should afford a safe retreat for many generations to come for one of the closest of man's surviving relatives

Sir Thomas H Holland, Vice Chancellor of the University of Edinburgh, has been awarded the Gold Medal of the Institution of Mining and Metallurgy "in recognition of his eminent services to Geological Science and to the mineral industries during his tenure of high public appointments—notably those of Director of the Geological Survey of India and of Rector of the Imperial College of Science and Technology —and of his researches and publications upon the mineral resources of the British Empire and their relationship to national and international problems"

At a general meeting of the members of the Royal Institution, held on Mar 3, it was announced that the managers have elected Mr J B S Haldane Fullerian Professor of Physiology in succession to Prof J S Huxley. The Friday evening discourses after Easter will commence on May 2, when Mr H E Wimperis will give a discourse on "A Study of the Phenomenon of Spin in Airplanes" Successive discourses will probably be given by Prof J Garstang, Dr C M Yonge, Mr R S Whipple, Sir Harold Carpenter, and Prof H Clay

At the ninth annual dinner of the London section of the British Association of Chemists, held on Mar 1, Sir Arnold Wilson outlined a scheme which is now under consideration for a building to house the principal societies and institutions in London concerned with chemistry and chemical industry or related to them The societies interested are the Institution of Mining and Metallurgy, the Institution of Mining Engineers, the Chemical Society, the Society of Chemical Industry, the Institution of Chemical Engineers, the Institution of Rubber Industry, the Institution of Petroleum Technologists, the Institute of Fuel, the Institute of Metals, the Iron and Steel Institute, the Faraday Society, and the Physical Society It is proposed that all these societies should be housed under one roof and their libraries pooled for the common use of their members As Sir Arnold pointed out, the scheme has the advantage that each society would retain its own individuality while giving its members facilities for informal meeting with members of related societies It would thus be an important step towards the co operation and co ordination so necessary to day in allied branches of science and technology It was stated that £100,000 has already been promised in furtherance of the scheme

At a meeting of the Royal Society of Edinburgh held on Mar 3, the following were elected fellows of the Society Prof William Annan, Edinburgh, Mr D R R Burt, Colombo, Lieut Col John Cunningham, Edinburgh Lieut Col L M Davies, Edinburgh Dr A E M Geddes, Aberdeen, Dr Douglas Guthrie Edinburgh, Sir Thomas Holland, Edinburgh, Dr David Jack, St Andrews, Dr S G Jones, Glasgow, Prof P S Lelean, Edinburgh, Dr J W Low, Bristol, Dr A C M'Candlish, Sorbie, Mr W C Miller, Edinburgh, Dr J M W Morison, Edinburgh, Mr James Morton, Edinburgh, Prof Wm Oliver, Edinburgh, Principal G F O'Riordan, London, Mr A W Ritchie, Edinburgh, Dr David Russell, Leven, Dr F W Sansome, London, Mr E C Shankland, London, Dr R H Slater, Edinburgh, Mr J W Struthers, Edinburgh, Prof C W Stump, Sydney, Dr J D Sutherland, Edinburgh, Dr C I B Voge, Edinburgh, and Dr A C White, Beckenham

The Empire Marketing Board has made a grant to the New Zealand Department of Scientific and Industrial Research for research on fruit production and storage to be carried out in New Zealand Investigations will be pursued into cool storage, transport, disease and insect control, nutrition, physiological disturbances, and rootstock propagation of New Zealand fruit Valuable results have been obtained in the past, as the quality of fruit imported into Great Britain shows, but the work has suffered from lack

of continuity and field experiments At a conference held recently at Wellington between representatives of the fruit-growers, the Department of Agriculture, the Department of Scientific and Industrial Research, and the Cawthron Institute, it was decided to form a fruit research organisation for New Zealand Arrangements have been made to purchase an orchard, a research programme has been planned, and the Cawthron Institute and the Department of Agriculture have agreed to lend the members of their staff who are mainly engaged on fruit research A horticulturist is to be appointed to work on root stock improvement and introduction, and it is probable that he may first study methods and results achieved in Great Britain at the East Malling Research Station, where Mr R G Hatton is engaged on root-stock improvement and other activities with Empire Marketing Board funds New Zealand fruit growers are contributing substantially to the expenses of the scheme, and the remainder of the cost is being met by the New Zealand Government

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An engineer at the Building Research Station, Garston, near Watford, for work mainly in connexion with research on steel structures—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S W 1 (Mar 10) A public analyst for the City of London (Food and Drugs (Adulteration) Act, 1928) and agricultural analyst for the City and Port of London (Fertilisers and Feeding Stuffs Act, 1926)—The Town Clerk, Public Health Department, Guildhall, E C 2 (Mar 10) A lecturer in chemistry at the Widnes Municipal Technical College —The Clerk to the Governors, Municipal Technical College, Town Hall, Widnes (Mar 17) A woman sanitary inspector and health visitor for the Royal Borough of Kensington—The Medical Officer of Health, Town Hall, Kensington, W 8 (Mar 18) A resident lecturer in geography at the Diocesan Training College for Women Teachers, Derby—The Principal, Diocesan Training College for Women Teachers, Derby (Mar 21) An assistant on the higher technical staff of the Library in the Science Museum, South Kensington—The Director and Secretary, Science Museum, South Kensington, S W 7 (Mar 22) An organiser of agricultural education under the Administrative County of Cambridge—The Clerk of the County Council, County Hall, Cambridge (Mar 22) A lecturer in metallurgy at the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (Mar 28) An assistant to the Chief Officer of the Imperial Bureau of Fruit Production—The Chief Officer, Imperial Bureau of Fruit Production, East Malling Research Station, East Malling, Kent (Mar 31) An assistant lecturer in geography in the University of Birmingham—The Secretary, The University, Birmingham (April 26) A professor of zoology in the University College of North Wales—The Registrar, University College of North Wales, Bangor (May 5) A secretary to the Lagos Executive Development Board, Nigeria—The Crown Agents for the Colonies, 4 Millbank, Westminster, S W 1 (quoting M/2029) A sanitary inspector under the Sudan Medical Service—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W 1

Our Astronomical Column

Report of the Paris Observatory for 1928 —This report contains an interesting summary of the recent comparison of longitudes of various observatories by wireless signals, which was organised by M B Baillaud and General Ferrié

The following are three arcs girdling the world

Algiers to San Diégo	8^h	0^m	56	$900^s \pm 0\ 002^s$
San Diégo to Zi Ka Wei	8	5	28	$731 \pm 0\ 006$
Zi ka Wei to Algiers	7	54	34	$362 \pm 0\ 006$

The sum of the three shows an error of only 0 007 sec

The difference Paris Greenwich comes out $9^m\ 20\ 914^s$, which is less than the "Nautical Almanac" value by only $0\ 016^s$ There was formerly an appreciable difference between the English and the French determinations of this arc, but they have now been brought into satisfactory accord

The catalogue of 10656 "étoiles de repère" for the Astrographic Catalogue is on the point of being issued

Dark Objects in Barnard's Photographic Atlas — In a fifth note on the dark objects in Barnard's Photographic Atlas, published in the *Atti della Pontificia Accademia della Scienze* (*Nuovi Lincei*) for 1929, Prof G Hagen of the Vatican Observatory points out that the last ten plates in Barnard's Atlas confirm the suggestion of the preceding forty plates, that not a single one of the dark objects selected by Barnard for his two lists differs in any way from W Herschel's fifty two extensive nebulosities Moreover, all of those within reach of the Vatican refractor could be estimated in density on the numerical scale with which all Herschel's regions were examined It may safely be concluded that all the dark markings represented on the fifty plates of the Atlas, whether selected or passed over by Barnard, correspond with the Herschel regions

Distribution of Stars of Different Spectral Types — Dr Otto Seydl of Prague has published a series of maps which give the distribution of stars of the different spectral types referred to galactic co ordinates The stars of types *B*0 to *B*5 are confined to a narrow belt along the galaxy Those of *B*8 to *A*3 are in a wider belt, with a few islands in higher latitudes, in the next map, *A*5 to *F*2, the galaxy is still discernible as a richer region, but there is a strong minority in higher latitudes, the same description applies to the next two maps, *F*5 to *G*0 and *G*5 to *K*2 For *K*5 to *Mc*, galactic concentration is again strongly in evidence, but less so than in *B*0 to *B*5 There is a final map showing all types combined, naturally the whole map is fairly full, but the galaxy is by far the richest region Star density is indicated by depth of shading in the manner adopted to show ocean depths The Henry Draper Catalogue was used in preparing the maps, which include stars of magnitude 7 0 and brighter There is a description (in English) of the maps, together with tables, the whole forms Cis 6 of the *Publications* of the National Observatory of Prague

Research Items.

Pictographs on European Prehistoric Pottery.—We have received from Dr. L. A. Waddell a questionary on the Sumerian markings upon prehistoric pottery found in the Danube and associated valleys of Middle Europe. In an explanatory note Dr. Waddell appeals to archæologists and historians in middle and south-eastern and northern Europe, and particularly to prehistorians in the British Isles, to examine all examples of prehistoric pottery from the area mentioned to which they have access for markings, apart from the decorative element, in the nature of owner's or maker's marks. The object of the search, it is explained, is to demonstrate that these markings are analogous to the 'owner's marks' inscribed on the pottery of the Predynastic and First Dynastic periods in ancient Egypt. The latter, Dr. Waddell maintains, can be shown to be Sumerian pictographic writing and presumably bear their phonetic values. By means of a comparative table of marks, Dr. Waddell seeks to demonstrate their identity in Sumerian, Egyptian, and Danubian pottery marks, giving their phonetic equivalent in each case. Dr. Waddell also holds that he has demonstrated that all the ancient civilisations of the world—Mesopotamian and Elamite, Egyptian, Minoan, Hittite, Græco-Roman, Indo-Persian, and presumably also Chinese, were derived from Sumeria. By a synchronism of ancient Egypt and Mesopotamia, Menes is identified as a son of Sargon of Akkad and his date fixed at about 2703 B.C., while for the Danubian pottery from the prehistoric strata at Vinča, a date of about 3300 to 2700 B.C. is suggested on palæographic grounds.

Sacred Trees in Egypt.—In *Man* for January, Mr. G. D. Hornblower describes with photographs a sacred grove at Nezlet Batran in Egypt, which differs from most sacred groves in that country in that it is not connected with any holy personage. Sacred trees, mostly sycamore, are common in Egypt, normally in association with sheikhs or their tombs. On them rags from the clothing of their devotees are frequently hung. The Virgin's Tree at Matarieh, near Cairo, is a well-known example and has been the object of pious pilgrimage for Christians for centuries. Under it the Virgin is said to have rested with the Holy Babe, and here only was true balm grown, originating in water from the Infant's clothes which the Mother washed out in a neighbouring pool. The grove at Nezlet Batrân is known as *Dahr es Sunt*, "The Back of the Acacias." The fact that it is not associated with a Moslem or Christian saint suggests that here the belief has survived from very early times in considerable purity. It is sacred to the *Sukkan es Sunt*, "The Inhabitants of the Acacias"—supernatural beings who live underground. It is visited on Friday mornings, and its leaves dried and powdered are burned as incense for the healing of the sick. No man may use its wood for fuel under penalty that evil, such as fire, will strike his house or he may lose his cattle through sickness. It shares with other sacred trees two features. Lighted lanterns are hung on the branches, and iron nails are driven into the trunk as offerings for sick people. These must be fresh from the forge.

Biological Control of the Gipsy Moth.—In *Technical Bulletin* No. 86 of the United States Department of Agriculture (1929) Messrs. A. F. Burgess and S. S. Crossman discuss the results of twenty-four years of work with reference to this problem. Both the gipsy moth and the brown-tail moth are well-known introduced pests of the United States and the present report reviews the work done in controlling these insects by the introduction of their natural enemies from Europe. It is claimed that by introducing insect parasites against the gipsy moth, the forests of New England have been saved from destruction. From 1905 to 1916 defoliation showed no reduction in intensity, but, from 1920 to 1924, the acreage defoliated gradually decreased, until in the latter year few completely defoliated areas remained. The total percentage parasitism resulting from the activities of beneficial insects gradually increased until the maximum was attained in 1923. Since then, the parasitism has steadily declined until 1927, when some revival was noticed. The authors state that unless the parasites increase again more rapidly, the westward spread of the gipsy moth will have greatly reduced chances of being checked. During the decline of the parasitism the gipsy moth has greatly increased again and, in eastern Massachusetts, it regained its former severity. In forest areas, where artificial control methods, other than the elimination of favoured food plants, are not applicable, the sole chance of repression, without undue expense, lies in biological means. Much work still remains to be done on the latter procedure, and investigations being made in the native countries of the gipsy moth lend support to the possibility that improved methods and results will follow. In towns and cities, on the other hand, artificial control, although expensive, can be employed and yields good results. A combination of both methods of campaign, according to the type of country in question, requires continued rigorous prosecution.

Pliocene and Pleistocene Fossils from Sakhalin.—The northern half of the island of Karafto, or Sakhalin, has long been known to yield rock oil in the regions bordering on its eastern coast. During the occupation of the island by the Japanese, regular surveys of these districts were made and fossils collected, many of which, however, were destroyed in the fire following the great Tokyo earthquake of 1923. The remainder, with some additional material and specimens collected farther south, where oil does not occur, have now been described by Prof. Matajiro Yokoyama (*Jour. Fac. Sci., Imp. Univ. Tokyo*, sect. 2, vol. 2). Forty-two species of marine mollusca are described and referred to the Pliocene, while a few from the southern locality are ascribed to the Pleistocene. From a study of these the author is led to infer that whereas in similar deposits in Japan proper and in Formosa the evidence, as pointed out in previous papers, indicates a colder climate then existed than at the present day, no such difference seems to have occurred in Sakhalin. Further studies on this point are nevertheless necessary.

After-Shocks of the Tango (Japan) Earthquake of Mar. 7, 1927.—Mr. N. Nasu, of the Tokyo Seismological Institute, has recently made an exhaustive study of the after-shocks of the Tango earthquake (*Jour. Fac. Sci., Tokyo Imp. Univ.*, vol. 3, pp. 29-129; 1929). These shocks were so numerous that at one station 1307 shocks were recorded up to the end of June 1928. Of these it was found possible to determine the surface position and depth of focus of 482 shocks. The sites of the shocks changed from time to time within a limited area near the two new faults, the most active zones lying to the west of the Gomura fault, and to the south of the Yamada fault. From the distribution of the epicentres, it is inferred that the Gomura fault may extend under the Japan

Sea to a distance of 18 miles from the coast, so that its total length may be more than 30 miles, while that of the Yamada fault may be 18 miles Plotting the positions of the foci on horizontal and vertical planes, Mr Nasu shows that they lie on series of parallel planes from one to three miles apart, the sensible shocks being caused by the formation of large cracks, and the insensible shocks as a rule by the growth of small secondary cracks that were very numerous near the principal faults A clinograph, erected near the central region of the earthquake, showed that the ground tilted for a few days before each after shock of moderate strength, the tilting being towards or from the epicentre according as it lay in a region of subsidence or elevation during the principal earth quake

Samarskite from New Mexico —A detailed study of the samarskite from a mica pegmatite near Petaca in the north central part of New Mexico has been made by F L Hess and R C Wells, and their results are published in the January number of the *Amer Jour Sci*, 1930 The mineral is shown to be composed of two parts one approximating to $2Y_2O_3$ $3Cb_2O_5$ and the other to Y_2O_3 Cb_2O_3 Detailed analyses are given from which the following data are quoted

	I	II
U	10 66	4 85 per cent
Th	1 39	0 97 ,,
Pb	0 40	0 10 ,,
$\frac{Pb}{U + 0\ 38\ Th}$	0 038	0 019
Age	280	140 millions of years

Radiographs show that I is an older mineral which was partly replaced by II by later solutions flowing along cracks The results indicate that the variable results in age calculations on minerals from the same pegmatite are due to successive periods of mineralisa tion The evidence supports the thesis of Hess that many pegmatites are the product of successive re placements, and it further explains satisfactorily the puzzling fact already recognised by Holmes, Ells worth, and Kirsch, that minerals from the same petrographic province may show very different ages as tested by their lead ratios It is suggested that the radial cracking of pegmatite around minerals may be due to the growth of new minerals being faster than the replacement of the older material

The Behm Limno-Sounder —A useful echo sounding machine for use in shallow water from small craft, such as motor boats and rowing-boats, is described in the *Hydrographic Review*, vol 6, No 2 The Behm Limno Sounder is operated with 12 volts, and power is supplied from dry cells or a storage battery It is made of light metal, and has a range up to 200 metres, and shows the depths in metres When the vessel is stopped, the range is greater than when the vessel is under way Soundings may be repeated at intervals of a little less than one second The transmitter and receiver may be permanently fixed to the vessel's side or bottom, or, if more convenient, may be slung over the side by a rope when required The depth is shown by the reflection of light A point of light moves along the scale, and the length of the line of light is the measure of depth The same apparatus mounted on a tripod is adaptable to soundings from an ice covered sea or lake Its operation is unin fluenced by low temperatures A special form of this sounder lowered by a cable and provided with floats could, it is claimed, be used from an airship

Surface Tension and Temperature —In the issue of the *Physikalische Zeitschrift* for Jan 1, Dr N Bar bulescu, of the Physical Chemistry Laboratory of the University of Klausenburg, Rumania, sums up and extends his endeavours to express by a satisfactory formula the variation of the surface tension α of a liquid with temperature He introduces the idea of a surface tension of the gas or vapour above the liquid and makes the observed surface tension the difference between the true surface tensions of liquid and gas or vapour It is also assumed that it varies as exp $-a/(T_c - T)$ where a is a constant and T_c the critical temperature of the liquid On these assumptions, he arrives at the relation $\alpha V^{2/3}$ pro portional to $(T_c - T)$ exp $-a/(T_c - T)$, which he shows fits the observed values very well for a number of normal liquids, except close to their critical points For abnormal liquids he makes a a linear function of $T_c - T$ and states that a still more accurate expres sion $\alpha V^{2/3} = (A + BT + CT^2)(1 - p/P)$ where A, B, and C are constants, p the saturation vapour pressure at T and P at T_c, may be used up to the critical point

Range of Electromagnetic Waves —Mr V T Saunders has prepared a chart, based upon one ex hibited by the Royal Society at the British Empire Exhibition at Wembley, showing the range of electro magnetic waves (size 6 ft × 1 ft 10 in (London John Murray, 1930) Unmounted, 4*s* 6*d* net, mounted on linen, 8*s* 6*d* net, mounted on linen, folded, 10*s* 6*d* net, mounted on linen, varnished, on rollers, 12*s* 6*d* net) The chart covers the whole range of the electromagnetic spectrum between the cosmic rays and the waves produced by mechanical movement of a coil in a magnetic field Wave lengths are shown both in centimetres and in Ångström units, together with the corresponding frequencies, and summaries are given of how the waves in each range are generated and detected There are two errors under the head of the detection of X rays It is not necessary for a body to be heated for it to emit electrons under their action (*e*), and it is at least mis leading to state without further detail that X rays show no ordinary reflection or refraction (*f*) Apart from these two points, the chart is accurate, and is likely to find a home on the walls of most elementary laboratories

Rapid Chemical Changes —The February number of the *Proceedings of the Royal Society* contains two papers by Dr F J W Roughton on heat effects in rapid chemical changes The time required for com pletion of a reaction is often a very small fraction of a second, if the reacting materials are in good contact, and the measurement of this time, or the setting of an upper limit to it, especially if coupled with a deter mination of the thermal effect, calls for a special technique Dr Roughton has applied for this pur pose a modification of the method used by him and Dr H Hartridge for studying the velocity of rapid reactions, the reagents are mixed whilst travelling at high speed through an observation tube, and the temperature of the mixture read at various points by delicate thermocouples, time intervals being deduced from the speed of flow of the fluid After an ex haustive inquiry into the possible sources of error, Dr Roughton concludes that it is possible to measure absolute temperatures in the mixture to an accuracy of 10^{-3} deg C, and temperature differences to somewhat less The order of magnitude of the time intervals involved is indicated by his result that the total heat of neutralisation of most acids and bases is liberated within a period of less than one hundredth of a second Attempts are now being made to extend the accuracy of the temperature measurements to 10^{-4} deg C, which will permit of the study of some reactions of considerable physiological importance

Gramophone Records of Acoustic Analyses.

AT a meeting of the Physical Society of Sheffield held at the University of Sheffield on Feb 11, a number of special gramophone records prepared in the Bell Telephone Laboratories, New York, to illustrate certain phenomena of hearing, were demonstrated by Dr W H George In the preparation of the original records the usual electrical process was used to convert the sound-waves by means of a microphone and amplifier into fluctuating electrical currents which, in passing through an electromagnetic recorder, operate the stylus cutting the 'wax' In addition, electric filters could be switched into the circuit so as to eliminate effectively known frequency ranges

Three of the records demonstrate the striking discovery of Fletcher (*Phys Rev*, 23, p 427, 1924) that, contrary to the usual conception, the pitch of a musical sound is *not* necessarily that of the lowest component vibration A single note (C = 256 vib per sec) is played successively upon a piano, a 'cello, and a French horn, and then the notes are repeated with the filters adjusted to eliminate the fundamental tone, then the fundamental and the first two overtones, and later all below the sixth or eleventh overtones Although great differences in quality and intensity are apparent, the pitch of the notes heard remains the same Quality differences sometimes make it difficult to decide if the pitch is middle C or one of its octaves The experiments and results are repeated with the sung vowel Ah, with an organ pipe and with a clarinet, in which latter instrument the lower even overtones are very weak

Low pass filters are used in another record to illustrate the effect on tone quality of removing the upper partials from the tones of a single note played upon a piano, 'cello, or French horn The filters are adjusted to give successively the fundamental, and then no overtones above the first, fourth, ninth, and seventeenth Notable changes of quality and loudness are observed depending upon the relative intensity of the various overtones for each instrument When the fundamental only is recorded the instruments are almost indistinguishable, but the slight difference which remains when allowance has been made for the intensity differences and for a certain difficulty of the horn player getting the correct note, suggests that the quality of a musical note depends also upon the rate of growth and decay, and it would be interesting to hear the effect of various amplitude changes imposed upon a tone which when sustained was pure and of single frequency

The remaining records deal with the quality changes produced in much more complex sounds consisting of a short musical passage played by a number of instruments and with a passage spoken by the normal voice The original sounds cover a normal range of frequencies, and the filters introduced pass only the frequency ranges 375 2500 or 750 1250, below 1250 or 2500 or above 375 or 1250 vibrations per second The effects of an overloaded amplifier with and without a middle pass filter are illustrated and the characteristic high hissing sound appears well in the spoken passage Filters are not used in two of the records which demonstrate the effects of reductions in the general intensity of the same complex sounds The intensity level is lower by steps of 1, 3, 5, 10, 20, and 30 transmission units (or decibels) Incidentally, these two records enable the hearer to obtain an idea of the scale of this unit which is being generally adopted

Apart from the general interest of the records, it would appear that, provided we regard a good gramophone as fairly common, then the three records illustrating Fletcher's work on perception of pitch form the first example of a research worker in acoustics presenting results originally obtained with complex and expensive apparatus in such a form that the actual phenomena involved can be experienced by others not so equipped The records may then be regarded as the analogues of the spectrum or X-ray photographs presented in papers dealing with other branches of physics

Common Commercial Timbers of India and their Uses

THE technical publications of research institutes have rarely much attraction for the layman, nor are they commonly read by members of trades to whom they would prove useful With this truism in mind, Mr H Trotter, forest economist at the Forest Research Institute at Dehra Dun, has recently prepared a brochure entitled "The Common Commercial Timbers of India and their Uses" (Calcutta Government of India Central Publication Branch, 1929), designed for the use of timber merchants and other users of Indian timbers

This booklet is based, as the author admits, on one drawn up in 1912 by his predecessor, Mr R S Pearson, entitled "A Commercial Guide to the Forest Products of India" Mr Trotter's work shows the great advance in knowledge in these matters which has been made since 1912 In the preface the author states "A great deal has been written of late years concerning the 'vast forest wealth' of India The fact remains, however, that except for teak and a few parcels of other timbers from Burma, Madras, and the Andamans, there is practically no export of timber from the country In the same way, the Indian markets concentrate on teak, sal, deodar and a few other well known woods, while local craftsmen content themselves with the cheapest timber available, whether suitable for the purpose for which it is intended or not"

Two factors are bringing about a change in the conservative ideas which have so long persisted throughout India The first is the prohibitive prices to which the more commonly used valuable timbers have risen, the second, the valuable work carried out at the Research Institute during the past eighteen years As is obvious from his work, Mr Trotter regards the forest wealth of India from the purely timber point of view Writers with perhaps a wider experience when alluding to the "vast forest wealth" of the country have not been so limited If some of the most valuable timbers of the country were eliminated from the account, the value of India's forest wealth, regarded from the point of view of the requirements of the greater bulk of its population, would still be enormous, and to this may be added an increasing number of minor products of the forest the potential value of which is at present not computable

The author divides his work into several chapters, dealing with the storage of logs in log ponds (the method being described and illustrated); air-seasoning —a section which will well repay careful study—kiln seasoning, preservation of timber by impregnation, and a chapter describing various common Indian woods This latter chapter is of importance, since, from the experience gained at Dehra Dun, it has proved possible to modify some of the descriptions

in old text books of Indian timbers, for example, Gamble's "Manual of Indian Timbers"

The practical user of timber, as also the forest officer, will probably find Chap vi, "Woods recommended for Special Uses", of the highest interest It is certain that this chapter best illustrates the remarkable progress in our knowledge in these respects which has resulted from the work of the research institute at Dehra Dun The author points out that there is a wide range between the cork like wood of *Erythrina* and the iron like hardness of 'pyinkado', and that only research and trial will enable each timber to be allotted to its best purpose, this is the work the economic side of the Institute has been engaged upon "As the work of research proceeds, it becomes more and more evident that India possesses timbers which are unsurpassed by any other country, but the practical utilisation of the lesser known timbers has been hindered by a curious circumstance This circumstance can be summed up in the one word 'teak' For years past, teak has been the watchword in India It is what one might call a fool proof wood, and its durability and adaptability soon made it famous throughout the world With such a timber available in good quantities, Indian users looked no further for possible substitutes, until the inevitable began to happen, and supplies became more restricted, resulting in a very rapid rise of price Then, at last, India began to look to the rest of her timbers, and although considerable progress has been made to date, it will be some years yet before she knows exactly what her resources in this direction are, and still more time will be required before the industrial world is satisfied that these other timbers will answer the purpose for which they are required In addition to teak, such timbers as sal (*Shorea robusta*), deodar, chir (*Pinus longifolia*), sissoo (*Dalbergia sissoo*), and a few others, were used fairly extensively in those parts where they occurred, but beyond these, the commercial exploitation of the many hundreds of other so called Indian 'junglewoods' was a thing unknown"

The author divides this section into constructional woods, woods used in contact with the ground, woods used in contact with water, in boat and ship building (the best Burma teak known as 'Admiralty Teak' still reigns supreme), joinery and cabinet making (a number of species are enumerated), cart and carriage-making, cooperage, packing cases, and various miscellaneous articles A perusal of this chapter renders it evident that India could, and probably will, become entirely self supporting in articles the raw material of which is timber, and that in the future the people will be weaned from the old ideas which confined utilisation to teak, sal, deodar, and one or two others, for this chapter shows that already a variety of other Indian timbers are being brought into use

Mr Trotter is to be congratulated on a very valuable and useful piece of practical work which, *du reste*, is suitably illustrated

Larval Crabs

An important addition to our knowledge of development in the Brachyura is contained in Hiroaki Aikawa's recent work "On Larval Forms of some Brachyura" (*Records of Oceanographical Works in Japan*, vol 2, No 1, 1929) The author has hatched out the young of twenty four species of Japanese crabs, and from these first zoeas each genus can be quite easily recognised

Previous writers have used mainly the form of telson, presence or absence of spines on carapace, and the antennæ, as diagnostic characters of crab zoeæ, and those hitherto known can be classified by such characters, together with a knowledge of the number of zoeal stages The present author gives prominence also to the chromatophores, giving them a foremost place There is no doubt that these chromatophores are of importance, the disadvantage in using them is their comparatively fleeting nature Although Mr Aikawa states that the primary chromatophores (which alone are used) remain for a long time in preserved material, they undoubtedly do disappear eventually Taken together with the other characters, however, they are of considerable value

The system of classification given, based on the first zoeas only, is good, and shows that the Japanese crabs studied fit well into the usual scheme of classification It is to be hoped that further study will be made of the later stages and megalopæ A knowledge of these, together with number of zoeal stages, is much wanted The Oxyrhyncha having been shown in all known forms (with a few doubtful exceptions) to have only two zoeal stages, necessarily develop much more quickly than the Brachyrhyncha, and even in the first zoea this difference can be seen

The crabs described belong to various groups and families most of the larvæ being described for the first time, and the first zoea is in many cases compared with those from other countries, fitting in well with previous observations If such a study were to be made in all parts of the world we should have a real foundation on which to work in order to form a scheme of classification which would undoubtedly help the systematist for no systematic work can be complete without the thorough knowledge of all larval stages The paper is very well illustrated and is a welcome contribution to the literature on crustacean larvæ

University and Educational Intelligence

BIRMINGHAM —Dr J G Emanuel is to be invited to fill the vacancy in the joint professorship of medicine from the beginning of the summer term 1930

The following gifts have been received £350 from the Distillers Company, Ltd, for a post graduate research investigation in oil engineering, £100 from the Anglo Persian Oil Company and £100 from the Institute of Automobile Engineers, for research in oil engineering, mine rescue apparatus to the value of £210, from Messrs Siebe, Gorman and Co, and a collection of modern safety lamps, to the approximate value of £77, from several firms, for the Mining Department Mrs Frankland has presented to the Chemistry Department a bronze relief portrait of Prof P F Frankland, first professor of chemistry in the University

The following resignations have been received Mr T H Turner (lecturer in metallurgy), Mr L P Timmins (oil engineering), and Dr W C O Hill (anatomy) An additional assistant lecturer (Grade III) is to be appointed in the Department of Geography

EDINBURGH —The Court has agreed to subscribe to the Students' Hostel at Benmore, Argyllshire This Hostel, which was formerly the Mansion House of Benmore, has been presented to the Forestry Commission (Scotland) by Mr Harry Younger, who had previously given the whole estate to the Commission The house will be open to visiting students and members of scientific societies interested in sylviculture and botany from April 1 to Sept 30 in each year The policies, extending to 115 acres, including the gardens and arboretum, will be open to authorised visitors In addition, the adjoining and neighbouring estates

of the Forestry Commission, extending to 36,000 acres, will be available of access for educational purposes

Leeds —The University Council has recorded "its profound regret in the loss sustained by the death of Arthur Greenhow Lupton, the first Pro Chancellor of the University His long and continuous association with the Yorkshire College and University—a connexion unbroken for 55 years—lent to his counsel a supreme value, and to his advice the wisdom born of experience He had followed and accompanied every step in the growth of the Yorkshire College, and its gradual development to University status He presided over the board of Governors of the College from 1889 till 1904, and over the University Council from 1904 till 1920 The University acknowledges with pride that the distinguished place and high standing which it now occupies in the public opinion of Yorkshire and the country are in large measure due to the character and ideals of its first Pro Chancellor "

London —Dr H A Harris has been awarded the William Julius Mickle Fellowship for 1930 in respect of research work (radiographic and histological) during the past five years in connexion with problems of growth in man and animals

Dr Francis Davies has been appointed, as from Aug 1, to the University readership in anatomy tenable at King's College Dr Davies was educated at University College, Cardiff, and continued his medical studies at University College Hospital, London From 1924 until 1927 he was demonstrator, and since 1927 he has been senior demonstrator in anatomy at University College

Prof L T Hogben has been appointed as from Aug 1 to the University chair of social biology tenable at the London School of Economics In 1912, Prof Hogben entered Trinity College, Cambridge, with a major entrance scholarship, and in 1915 he obtained the Frank Smart Prize in zoology From 1919 until 1920 he was lecturer in zoology at Birkbeck College, and from 1920 until 1922 lecturer in the Department of Zoology and Huxleyan Curator at the Imperial College of Science In 1922 he was Mackinnon Student of the Royal Society He was at the University of Edinburgh from 1923 until 1925 as lecturer in experimental physiology, and at McGill University from 1925 until 1927 as assistant professor of zoology Since 1927 he has been professor of zoology in the University of Cape Town

Some attractive cinematograph displays of Empire films are being given at the Imperial Institute During the present month, films dealing with various aspects of life in Africa, the West Indies, the Antarctic, Australia, and India, and a natural history film are being shown for successive periods There are four sessions daily, except on Sundays, when there are two sessions Admission is free but seats are reserved on application in writing to the secretary of the Institute

The Foreign Work Committee of Leplay House is arranging to send a group of members and others to North Africa during the coming Easter vacation, under the leadership of Mr E M Keith Ellerton, of the University of Liverpool The route covered is Algiers to Biskra and Touggourt, then to Tunis via Timgad and Constantine Another group will go to Brittany, making Carnac its centre, for archæological studies, and another to Holland Those interested in field studies from the point of view of architecture, history, geography, and sociology should apply to Miss Margaret Tatton, Director, Foreign Work Committee, Leplay House, 65 Belgrave Road, S W 1

Historic Natural Events

Mar 11, 1669 Eruption of Etna —One of the greatest eruptions of Etna, preceded by violent earthquakes for three days, began by the opening of a fissure nearly 12 miles long on the south side of the mountain A new crater opened 8 miles west of Acireale, the ashes from which formed the double cone now known as the Monti Rossi The lava stream from the crater covered an area of about 40 sq miles It destroyed 14 villages, including Belpasso and Mascalucia, invaded Catania, mounting over the wall 60 ft high, and finally reached the sea in a stream 600 yards wide and 40 feet deep

Mar 11, 1912 Darkness and Black Rain —In the afternoon of Mar 11 a severe thunderstorm took place in the east of Hampshire and the west of Sussex A peculiar feature was the intense darkness that occurred near the centre of the storm The sky was described as of inky blackness, in other places the cloud was greenish yellow and dense fog was experienced The rain which fell from this cloud was black like ink, and smelt slightly of tar There seems little doubt that the blackness was actually due to London fog which drifted southwards before a light wind until it reached the thunderstorm area

Mar 11-14, 1888 'The Great March Blizzard' —This was the worst storm in the history of the eastern United States An elliptical trough of low pressure moved eastward, with two intense centres, the northern centre passed out over the Atlantic on Mar 11, while the southern centre turned north eastward and remained in the neighbourhood of Cape Cod from Mar 12 to 14, gradually becoming less intense On the western side of these two depressions intensely cold northerly winds blew with great force, the temperature being little above 0° F in the interior of Connecticut and New York, and the wind up to 70 miles per hour West of 72° W the snowfall was excessive, and piled up in immense drifts The average depth of undrifted snow exceeded four feet in parts of New York State, and caused almost complete cessation for several days of railway traffic entering New York City

Mar 13, 1252 Drought and Disease —This great drought was associated with persistent north, north-east, or east winds "On the 13th day of March there began a sore drought, continuing a long time The grass was so burned up in pastures and meadows that if a man took some of it in his hands it straight fell to powder, and so cattle were starved for lack of meat And because of the exceeding hot nights there was such abundance of fleas, flies, and gnats that people were vexed and brought in case to be weary of their lives And herewith chanced many diseases, as sweats, agues, and other In the harvest time fell there a great death and murrain amongst cattle, and especially in Norfolk, in the Fens, and other parts of the south This infection was such that dogs and ravens feeding on the dead carrion, swelled straightway and died, so that the people durst eat no beef lest the flesh haply might be infected "

Mar 13, 1523 Storm and Flood —A severe thunderstorm accompanied by violent winds broke over Holland, hailstones the size of hen's eggs fell A dam burst at Schalkwyk, causing great floods on the Leck from Schalkwyk to Leyden There were many thunderstorms throughout the following summer

Mar 13, 1924 Sun Pillar —A fine sun pillar was widely observed over southern and eastern England, including London, and also in Ireland At Turnham Green it was first seen at 5 45 P M, when it formed

a whitish vertical streak equal in width to the sun and reaching up to 5° above it The sun's disc was strangely distorted before it disappeared at 5 49, and the pillar remained visible until 6 9 At Golders Green at 5 30 it came out of the sun's disc like a tree trunk, red orange in colour, turning to gold and then becoming whiter Other observers described it as blood-red, apricot, or rose pink streaked with primrose yellow, but all agreed on its extreme beauty Some experienced observers estimated the height as 30°, though sun pillars exceeding 15° are exceedingly rare

Mar 15, 1889 Hurricane at Samoa —On Mar 15 the harbour of Apia, Samoa, was crowded by seven warships, one British, three American and three German, all of which had been sent there because of the strained political situation, as well as two merchant ships and two schooners On the afternoon of that day the island was struck by a violent hurricane from north north east (the harbour opens to the north), and all the vessels were either sunk or driven ashore with the exception of H M S *Calliope*, which was able to steam out of the harbour

Mar 15, 1929 Floods in Alabama —As a result of heavy rain at the end of February and early in March, the valleys of the Choctawhatchee and Escambra Rivers in Alabama were already saturated with water, when on Mar 13–15 further heavy rains fell over the district, reaching 29 6 inches in three days at Elba, of which 20 inches fell on Mar 15 (This amount is partly estimated, as the rain gauge was carried away by the floods after 14 inches had been recorded) The towns of Elba and Brewton, at the junctions of rivers, were flooded to a depth of more than 10 feet in places, and great damage was done, estimated at nearly five million dollars Owing to the flood warnings, no lives were lost

Societies and Academies

CAMBRIDGE

Philosophical Society, Jan 27 —**A F H Ward** A microcalorimeter A microcalorimeter was described accurate to 0 0005 cal The system liberating the heat fits closely inside a copper tube contained in a Dewar flask A series of iron constantan thermo couples has one set of junctions making good thermal contact with the tube and the others in a brass ring outside, kept in a thermostat They are connected to a sensitive moving coil galvanometer The Tian multiple walled thermostat is used—three concentric thick copper cylinders, insulated with kapok, the inner containing water The temperature of the outer cylinder is controlled with a mercury regulator, and the insulating layers cut down temperature variations so that the inner vessel is constant to less than 1/500,000 C°

PARIS

Academy of Sciences, Jan 27 —The president announced the death of General Sebert —**L Cayeux** The existence of two groups of Algæ with the structure preserved in the 'schisto limestone system' of the French Congo There is ground for supposing that, in the oolitic complex of the limestone schists of the French Congo, certain limestones of oolitic appearance are petrified Algæ —**Charles Nicolle, Paul Durand, and Ernest Conseil** Preventive vaccination against plague pneumonia by the respiratory tract In addition to the usual injection of dead plague bacilli, a method of inhaling a suspension of the serum as a spray was tried 866 cases were treated, and less than 1 per cent died of the plague —**Serge Bernstein** A class of polynomials of minimum deviation —**Louis Roy** The fundamental equation of shock waves on elastic surfaces —**G Friedel and R Weil** The influence of the symmetry of the medium on the symmetry of the crystalline forms —**Auguste Lumière and Mlle Anna Malespine** The impeding influence of gestation on the Arthus phenomenon —**Alexandre Ostrowski** Some generalisations of the Euler product $\prod_{\nu=0}^{\infty}(1 + x^{2\nu})$ —**S Stoilov** The topological character of a theorem on the meromorph functions —**W Břečka and J Geronimus** An inequality for monotone polynomials —**Henri Eyraud** The summation of divergent integrals in the theory of spectra —**M A Andronow and A Witt** The mathematical theory of auto oscillations —**F Campus** The mean fibre of large hyperstatic arches —**Maurice Lambrey** The influence of foreign gases on the absorption spectrum of nitric oxide —**Félix Ehrenhaft** Magnetophotophoresis and electro-photophoresis A description of the phenomena observed when submicroscopic particles are examined under the microscope in a powerful magnetic field and in an electric field —**J J Trillat** The structure of gelatine The results of an X ray study of films of gelatine —**Jean Dalsace, M Gory, and Nemours-Auguste** An attempt on the radiographic visibility of the kidney Intra arterial injection of lipiodol, which is not toxic to the animal, brings out anatomical details in radiographs, especially in the kidney and suprarenal capsules —**J Décombe** The passage from the β ketonic esters to the β-amino esters The reduction of the azines or oximes of the β ketonic esters by the usual reducing agents does not give the amino esters, as might have been expected the reduction of the acetylhydrazones or benzoylhydrazones of these esters, however, gives the amino esters with fair yields —**L Haskelberg** Researches on the preparation of the glycerol esters of the amino acids —**Augustin Boutaric and Mlle Madeleine Roy** Researches on the sedimentation of suspensions of clay The results described are in general agreement with those obtained by Dubrisay —**H Besaire and Mlle E Basse** New stratigraphical and palæontological observations on the upper Cretaceous of the province of Maintirano (west of Madagascar) —**Ch Brioux and Edg Jouis** The correlation between the fineness and the solubility in carbonic acid of powdered limestones, and their neutralising action on acid soils The availability for agricultural purposes of powdered limestone is shown to depend on its state of division The neutralising action in the soil is in direct relation with the rate of solution in solutions of carbon dioxide A commercial method of valuation based on these facts is suggested —**P Chevey** Various rhythms other than thermal rhythms capable of marking the scales of fishes of the intertropical zone —**E Kohn-Abrest, Mlle Hélène Villard, and L Capus** The presence of thiocyanates in the human organism The post mortem transformation of veronal, dial, gardenal into cyanogen compounds Consequences in toxicology It is known that hydrocyanic acid under the influence of putrefaction can be partially converted into thiocyanic acid, and the presence of the latter is frequently the only proof of poisoning by a cyanogen compound Human viscera, even after much putrefaction, are normally free from thiocyanates, but after the administration of veronal, dial, or gardenal, appreciable quantities of thiocyanates can be found These new facts must be taken into account by toxicologists

COPENHAGEN

Royal Danish Academy of Science and Letters, Nov 15 —**Elis Strömgren** Continued researches on the restricted problem of three bodies Continued

researches on asymptotic solutions in the restricted problem of three bodies have led to the discovery of a whole system of hitherto unknown classes of periodic orbits

Nov 29—**Harald Bohr** (1) On integral functions General solution of a problem proposed by Borel—(2) On analytic, almost periodic, functions—**C Wesenberg-Lund** Contributions to the biology of the Rotifera (2) Deals mainly with the sexual biology of the Rotifera, studied for several years in a series of ponds in the northern part of Seeland—**Ojvind Winge** Sex-determination in the Cyprinodont *Lebistes reticulatus* In *Lebistes*, individuals with two X-chromosomes are generally females and XY-individuals are males As an exception XX males are produced, owing to genes, outside the Y chromosome, pulling in male direction This observation explains to a certain degree the peculiar disagreement between the sex-determination in *Lebistes* and the closely allied genus *Platypœcilus*, where the males have XX and the females XY chromosomes

ROME

Royal National Academy of the Lincei, Nov 3—**C Foà** and **A Peroni** First attempts to register action currents of the acoustic nerve—**P Tortorici** The principle of the arithmetic mean—**A M Bedarida** The theory of ideals of a finite algebraic body (4)—**I Todros** Projective differential investigations on pairs of plane lines or of surfaces—**E Gugino** The validity and extension of the theory of maximum effort—**G Supino** Certain integral properties of cubic expansion For certain investigations to be published shortly, use has been made of the following integral relations concerning the cubic expansion Θ of an elastic solid S subjected to external forces in equilibrium acting only on its surface σ

$$(1) \qquad \int_S \Theta dS = \frac{mE}{m-2}\int_\sigma (xP_x + yP_y + zP_z)d\sigma, \text{ and}$$

$$(2) \qquad \int_S y\Theta dS = \frac{mE}{m-2}\int_\sigma \left(xyP_x + \frac{y^2 - x^2 - z^2}{2}P_y + yzP_z\right)d\sigma$$

With these as starting point, it is shown that, if a system of forces in equilibrium (with components P_x, P_y, P_z) acts on a single plane zone σ, of an elastic solid, the total cubic expansion caused in the solid by these forces is zero—**E Raimondi** The dynamic effect of a translatory circulatory current investing a thin cylinder in the neighbourhood of an indefinite plane wall—**G Wataghin** An application of relativity to quantum mechanics The principal differential equations used in quantum mechanics and in the theory of relativity may be derived from a single variational principle—**M Merola** The variability of Y Canes Venatici—**P Tortorici** New determination of the local deviation in latitude and in longitude at the Astronomical Observatory of Palermo—**F Scandone** The Hall effect with extended electrodes (3)—**L Mascarelli** and **D Gatti** Contribution to the knowledge of diphenyl and of its derivatives (5) To obtain derivatives of diphenyl, use has been made of various methods which serve to prepare the corresponding derivatives of benzene—**O Cantoni** Investigations on the supposed existence of pulmonary lipo-dieresis Experimental results, obtained under various conditions, fail to confirm the hypothesis of pulmonary lipo dieresis

VIENNA

Academy of Sciences, Nov 28—**M Beier** Zoological expedition to the Ionian Islands and the Peloponnesus (6) Fishes worked out by M Holly—**E. Schweidler** The disintegration constant of radium D—**H Hornich** The complete independence of Menger's axioms of dimension—**F Morton** Measurements of brightness with grey-wedge photometers on a sea voyage from Europe to Guatemala and in Guatemala, 1928–29 The exposed strips of photometer paper wrapped in tinfoil were sent back every four weeks to the observatory at Davos Platz for development The values found for insolation were less than those at Davos

Dec 5—**A Köhler** Geological and petrographical investigations into the deeper rocks of the Lower Austrian Waldviertel and its boundary regions (1)—**A Köhler** Chemical analysis of the hornstone rock of Niederndorf near Erlauf, Lower Austria—**M Beier** Zoological expedition to the Ionian Islands and the Peloponnesus (7) Ixides worked out by P Schulze—**A Zinke** and **R Wengen** Perylene and its derivatives (28)—**K Ehrenberg** A remarkable bear's skull from the Bärenhöhle near Winden in Burgenland—**G T Whyburn** The sum of regular curves

Dec 12—**F Becke** The systematics and nomenclature of the 32 symmetry classes of crystals The German mineralogical society discussed this matter in Duisburg in 1926 and in Breslau in 1927 F Becke, E Schiebold, and F Rinne expressed themselves in lectures at Breslau, and F Rinne has put his proposals in final form in 1929 in Vol 50 of the *Abhandlungen* of the Saxon Academy—**W Schmidt** and **P Lehmann** Experiments on the 'breathing' of soil Under oscillations of atmospheric pressure the air in the soil is movable—**A Dadieu** and **K W F Kohlrausch** The Raman spectrum of organic substances Various substances were tried, esters and salts of acetic acid, derivatives of benzol The acetone line λ3008 was not verified—**K Przibram** Remarks on natural blue rock salt There may be layers in the crystals corresponding to cubic and other layers corresponding to rhombic dodecahedral surfaces Secondary recrystallisation is a possibility—**G Schaum** Communication of the Radium Institute No 245a Action of β and γ rays on electrolytic solutions A capillary tube with 30 mgm radium was submerged in a concentrated solution of silver nitrate for two months A grey precipitate formed

Jan 16—**L Moser**, **K Neumayer**, and **K Winter** Determination and separation of rare metals from other metals (19) New methods for the separation of titanium from other elements Tetravalent titanium can be precipitated in sulphuric acid solution by means of tannic acid and antipyrine—**A Kailan** and **A Ostermann** Velocity of esterification with ethyl-alcoholic, ethylene glycolic, and glyceric hydrochloric acid—**H R v Gaertner** Geology of the Central Carnic Alps A great number of new fossil finds in Silurian, Devonian, and Carboniferous strata, including graptoliths and trilobites in upper Silurian and cephalopods in upper Devonian—**J Schaffer** Change of function in gland organs of the skin The shrew mouse has skin glands commonly called sweat glands but secreting fat and albumen with a characteristic smell more probably these are scent or trail glands The water shrew has glands that swell in the breeding season, so also the sebaceous glands of the gemse The secretion in the gland bag of the badger seems to change from youth to age—**M Glaessner** The danic stage in the Gosau basin Conglomerates in the Salzkammergut—**R Ebner** and colleagues Hymenoptera from Palestine and Syria (Zoological expedition, 1928)—**P Esben-Petersen** Neuroptera (F Werner's zoological expedition to the Anglo Egyptian Sudan, 1914)—**F Werner** Scientific results of a zoological expedition to western Algeria and Morocco (3)—**J Hoffmann** Communication of the Radium Institute (246) Behaviour of ultramarine and of some natural and artificial silicates towards radium rays—**K Menger** Sketch of a new theory of measure Axioms of dimension and measure

Diary of Societies

FRIDAY, MARCH 7

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10 30 A M—G J Jenkins, Dr J S Fraser, and E B Barnes Discussion on Malignant Disease of the Ear

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 3 45—T B Layton Demonstration of The Rhinological Anatomy of the Naso-frontal Duct and the Hiatus Semilunaris.

ANDERSONIAN CHEMICAL SOCIETY (at Royal Technical College, Glasgow), at 8.15—Dr Cumming Lignin

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 4 30—The History of Mountains Opener Dr Harold Jeffreys

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5

INSTITUTION OF MECHANICAL ENGINEERS, at 6—J W Schuster The Strength and Design of Fusion Welds for Unfired Pressure Vessels

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at Engineers Club, Manchester) at 7—Dr F L Pyman Fine Chemicals

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7—A E Moore and W T Slater An Investigation of the Frequency Variations in Induction Watt-hour Meters

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Annual General Meeting), at 7

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Informal Meeting) (at Bolbec Hall Newcastle upon Tyne) at 7 15—W D Horsley and others Discussion on The Effect of the Use of Electricity in Workshops on Efficiency and Costs

JUNIOR INSTITUTION OF ENGINEERS at 7 30—Lt Col G J Hartley Chile and Engineering in Chile

INSTITUTE OF METALS (London Local Section) (at 83 Pall Mall), at 7 30—A Coad Pryor The Manufacture of Glass and some of its more Interesting Properties

GEOLOGISTS ASSOCIATION (at University College), at 7 30—Dr A E Trueman The Lower Lias (Bucklandi Zone) of Nash Point Glamorgan—A A Fitch The Geology of Etchingham and Robertsbridge Sussex—G S Sweeting The Geological Structure of the Ashburnham Battle and Crowhurst Districts Sussex with Notes on the Wealden Iron Ore

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8 30—Dr C Donald Spinal Analgesia with Spinocain—Dr H Jones Percain Ciba a New Regional and Spinal Analgesic with Special Reference to High Thoracic Nerve root (Splanchnic) Block

ROYAL INSTITUTION OF GREAT BRITAIN at 9—Dr C Tate Regan Angler Fishes

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (jointly with Glasgow Section) (at Institution of Engineers and Shipbuilders Glasgow)—J S F Gard and R F Robinson The Insulation of Heated and Cooled Surfaces

OXFORD UNIVERSITY JUNIOR SCIENTIFIC CLUB—Prof C E Inglis The Construction of a Great Suspension Bridge

SATURDAY, MARCH 8

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Annual District Meeting) (at Lecture Hall Taunton) at 11 A M

ROYAL INSTITUTION OF GREAT BRITAIN at 3—Sir Ernest Rutherford Atomic Nuclei and their Structure (I)

BRITISH PSYCHOLOGICAL SOCIETY (General Meeting) (at Bedford College) at 3 30—Dr V Hazlitt Children s Thought—Miss A M Jenkin Imagery and Learning

BRITISH ASSOCIATION OF MANAGERS OF TEXTILE WORKS (at Manchester Athenæum), at 6 30—F Nasmith The Increasing Use of Cotton Fabrics for Industrial Purposes

MONDAY, MARCH 10

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—C E Shattock Demonstration of Affections of Joints

KING S COLLEGE ENGINEERING SOCIETY at 5 15—A H S Oddy Pulverised Fuel

ROYAL AERONAUTICAL SOCIETY (jointly with Institute of Transport) (at Royal Society of Arts) at 6 30—Herr Wronsky Air Transport

INSTITUTION OF AUTOMOBILE ENGINEERS (Birmingham Centre) (at Queen s Hotel, Birmingham) at 7—W H Goddard The Mercedes Benz Diesel Engine

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle upon Tyne) at 7

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Section) (at Borough Polytechnic), at 7—L J Fowler Some District Heating Systems

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow) at 7 30—Annual General Meeting

MEDICAL SOCIETY OF LONDON, at 8—Dr J W McNee and others Discussion on Cardiac Infarction

SURVEYORS INSTITUTION at 8—Sir Harry Haward Recent Developments in Electricity Supply in Great Britain, with Special Reference to Rural Electrification

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8 30—F Kingdon Ward The Eastern Gate to India

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Bristol)

TUESDAY, MARCH 11

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Dr C Singer The Passage from Medieval to Modern Science (I) Science in the Middle Ages

INSTITUTION OF CIVIL ENGINEERS, at 6—H D Smith Reconstruction of Liskeard Viaduct, and Scheme for Reconstruction of the Approach Spans of the Royal Albert Bridge Saltash—F Gibbons Reconstruction of Approach Spans Royal Albert Bridge Saltash—J Alexander Reconstruction of Kent and Leven Viaducts, Furness Section of the London Midland and Scottish Railway

INSTITUTE OF MARINE ENGINEERS at 6 30—A T Wall The Advantages to the Shipowner of Closer Co operation between the Naval Architect and the Marine Engineer

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at North British Station Hotel, Edinburgh) at 7—Capt P P Eckersley Broadcasting by Electric Waves (Faraday Lecture).

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7—Annual General Meeting

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch—Burnley Section) (at Municipal College, Burnley), at 7 15—A. Sutcliffe Jobbing Castings

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Centre) (at King's Head Hotel, Coventry), at 7 30—Capt. J S Irving Problems Encountered in the Design of the *Golden Arrow*

Manchester College of Technology Textile Society (at Manchester), at 7 30.—J Innes Artificial Silk Manufacture
Quekett Microscopical Club (at 11 Chandos Street, W 1), at 7 30 —Prof R. R. Gates Vegetation and Man in the Canadian Arctic
Eugenics Society (at Linnean Society), at 8.—W A. Appleton and others Discussion on Unemployment.
Leicester Literary and Philosophical Society (Chemical Section) (at Museum, Leicester), at 8 —Discussion on The Profession of Chemistry
Royal Society of Medicine (Psychiatry Section) (jointly with British Psychological Society), at 8.30 —Discussion on The Rôle of Psychotherapy in the Treatment of Psychoses
Pharmaceutical Society, at 8 30 —Prof R V Wheeler The Chemistry of Coal

WEDNESDAY, March 12

Geological Society of London at 5 30 —R. W Pocock The Age of the Midland Basalts —Dr T Robertson The Origin of the Etruria Marl
Institution of Civil Engineers (Informal Meeting), at 6 —F M G Du Plat-Taylor Land Reclamation Work
Society of Chemical Industry (Newcastle Section) (Annual Meeting) (at Armstrong College, Newcastle upon Tyne) at 7 30 —J A. Reavell Some New Aspects of Evaporation
Royal Society of Arts, at 8 —Prof G Elliot Smith The Human Brain
Oxford University Junior Scientific Club.—Dr G Wachsmuth Cosmic Formative Forces in Earth and Man

THURSDAY, March 13

Royal Society, at 4 30 —V B Wigglesworth A Theory of Tracheal Respiration in Insects —H Raistrick and others Studies in the Biochemistry of the Lower Fungi
London Mathematical Society (at Royal Astronomical Society), at 5 —W N Bailey Some Classes of Functions which are their own Reciprocals in the Fourier Bessel Integral Transform —E T Davies The Equations of Gauss and Codazzi for Spaces with Torsion —D E Littlewood (a) Algebras in which the Equation $yx - xy = 1$ has a Solution, (b) Identical Relations Satisfied in an Algebra.—Prof L J Mordell (a) The Zeta Functions Arising from Quadratic Forms of which the Real Parts are Definite or Indefinite Forms, and their Functional Equations (b) Note on Kapteyn s and Bateman s Integrals Involving Bessel Functions —V Naylor Euler s Method of Summation
Royal Institution of Great Britain, at 5 15 —J B S Haldane Some Problems of Genetics
Society of Chemical Industry (Liverpool Section jointly with Institute of Chemistry—Liverpool and North West Section), (at Liverpool University), at 6 —W Doran Odour and Chemical Constitution.
Child-Study Society (at Royal Sanitary Institute), at 6 —R. A. Raven The New Prospect for our Adolescents Some Reflections
Institution of Electrical Engineers, at 6 —H A. Humphrey D M Buist, and J W Bansall The Imperial Chemical Industries Limited s Steam and Electric Power Plant at Billingham
Institute of Marine Engineers (Junior Section) at 6 30 —Engr Lieut. Comr H S Humphreys Marine Boilers Their Troubles and Maintenance
Royal Photographic Society of Great Britain (Colour Group—Annual General Meeting), at 7
Institution of Electrical Engineers (Dundee Sub-Centre) (at University College, Dundee) at 7 30
Optical Society (at Imperial College of Science and Technology), at 7 30.—T Smith Imagery Around a Skew Ray Part I Conjugate Points Part II Fourth Order Matrices for Skew Pencils Part III Sixth Order Matrices for Skew Pencils —Prof R A Sampson The Purpose and Design of the New Equipment at the Royal Observatory, Edinburgh —Adam Hilger, Ltd A Description of the Stellar Spectrograph for the 36" Reflector at the Royal Observatory, Edinburgh —Sir Howard Grubb, Parsons and Co A Description of the 36" Reflector at the Royal Observatory, Edinburgh
Institution of Automobile Engineers (Plymouth Centre) (at Devonport Technical College) at 8 —Capt L W Johnson The Inspection of Metals and their Alloys.
Royal Society of Medicine (Neurology Section), at 8 30 —Discussion on Injuries to the Brachial Plexus
North East Coast Institution of Engineers and Shipbuilders (Tees-side Branch).—A. Herbert, Ltd Films of The Age of Speed, and The 30th part of a Hair

FRIDAY, March 14

Biochemical Society (Annual General Meeting) (in Department of Physiology and Biochemistry, University College), at 3 —R A McCance and K. Madders The Comparative Rates of Absorption of Certain Sugars from the Human Intestine.—A. Hunter and J A. Dauphinee The Rate of Liberation of Arginine in the Tryptic Digestion of Proteins —Prof. A Harden and M. G Macfarlane Fermentation by Yeast Preparations.—G F Marrian and P F Marrian Microdeterminations of Hydroxyl Groups by Grignard s Reagent —G F Marrian (a) Further Observations on the Alcohol Isolated from the Urine of Pregnancy (b) An Improved Method for the Preparation of Œstrin The Isolation of Active Crystalline Material from Urine —B. Ahmad and Dr J C Drummond Observations on the Relation of Carotene to Vitamin A.—L F Hewitt Oxidation reduction Potentials of Cultures of Hæmolytic Streptococci —C A. Ashford The Phosphorus Distribution in Blood during Hypervitaminosis —R. A. Morton, I M Heilbron, and A. Thompson Some Further Observations on Vitamin A —R. A. Morton and I M Heilbron A Note on the Vitamin A of Butter —T Moore The Conversion of Carotene to Vitamin A *in vivo*. —F Dickens The Preparation and Properties of an Active Principle from the Urine of Pregnancy —K H Coward, K M Key, R. Morgan, and F J Dyer Variation in Vitamin A Assay
Royal Society of Medicine (Ophthalmology Section) (at Guy s Hospital), at 5 —Clinical Meeting.
Royal College of Surgeons of England, at 5 —Sir Frank Colyer Demonstration of John Hunter s Specimens of the Teeth
Physical Society (at Imperial College of Science and Technology), at 5
Malacological Society of London (at Linnean Society), at 6
Royal Meteorological Society (jointly with Royal Aeronautical Society) (at Institution of Electrical Engineers), at 6.30 —Dr F Nansen The Aims and Objects of the Aeroarctic.
Society of Chemical Industry (Glasgow Section) (Annual Business Meeting), at 6 45
Institution of Mechanical Engineers (Informal Meeting), at 7 —Exhibition of Industrial Kinematograph Films
Junior Institution of Engineers, at 7 30 —W A. Saille An outline of Siemen s No. 50 Telephone Switching equipment
Institute of Metals (Sheffield Local Section) (at Sheffield University), at 7 30.—A G Lobley Electric Heat Treatment Furnaces
Royal Institution of Great Britain, at 9 —Prof G Elliot Smith New Light on Vision.
Institute of Rubber Technologists (at Manchester Café, Ltd., Manchester).—G F Thomson Colours used in the Rubber Industry

SATURDAY, March 15.

Royal Institution of Great Britain, at 3 —Sir Ernest Rutherford Atomic Nuclei and their Structure (2).
Physiological Society (at University College).—Annual General Meeting
Royal Irish Academy (Dublin).

PUBLIC LECTURES

SATURDAY, March 8

Horniman Museum (Forest Hill), at 3 30 —Prof J R Ainsworth Davis Casting Life in New Moulds

MONDAY, March 10

Birkbeck College, at 5 30 —Prof V M Goldschmidt Chemical Geology (Succeeding Lecture on Mar 11)
University College, at 5 30 —Prof E J Salisbury Concerning The Study of Plants

TUESDAY, March 11

University College at 5 —Prof J C Brash The Growth and Developmental Mechanics of Bone (Succeeding Lecture on Mar 18)
King s College, at 5 30—Prof J H Muirhead Prospect and Retrospect in British Philosophy

WEDNESDAY, March 12

Royal Anthropological Institute (at Portland Hall Great Portland Street Extension of Regent Street Polytechnic), at 5 30 —Prof J L Myres The Early Use of Metals.
University College, at 5 30 —Prof J Steffensen Some Recent Researches in the Theory of Statistics and Actuarial Science (Succeeding Lectures on Mar 13 and 14)
British Medical Association (Tavistock Square), at 8 —Sir Andrew Balfour Health and Empire (Sir Charles Hastings Lecture).

THURSDAY, March 13

Sir John Cass Technical Institute (Jewry Street E C 3), at 8 —Prof T P Hilditch The Structure of Fats and its Bearing on their Utilisation

SATURDAY, March 15

Horniman Museum (Forest Hill), at 3 30 —H N Milligan Monsters of the Deep.

CONGRESS

March 12 and 13

Institute of Metals (at Institution of Mechanical Engineers).
Wednesday, March 12, from 10 a m to 12 30 p m.—Presidential Address
Dr D Stockdale The Composition of Eutectics
Dr T A. Rickard The Early Use of the Metals
From 2 to 4.—N P Allen Experiments on the Influence of Gases on the Soundness of Copper Ingots.
W E Prytherch Gases in Copper and their Removal
E J Daniels Unsoundness in Bronze Castings
R Genders Macrostructure of Cast Alloys. Effect of Turbulence Due to Gases
Thursday, March 13, from 10 a.m. to 1 p m —Dr D Hanson, S. L Archbutt, and Grace W Ford Investigation of the Effects of Impurities in Copper Part VI The Effect of Phosphorus in Copper
R. Genders The Aluminium Brasses
Dr C. F Elam The Diffusion of Zinc in Copper Crystals.
From 2 to 4 —L. Davies and L Wright Protective Value of Some Electro-Deposited Coatings
R. Lancaster and J G Berry A Note on Zinc-Base Die-Casting Alloys.
Prof B. P Haigh and B Jones Atmospheric Action in Relation to Fatigue in Lead
W R D Jones A Note on Metallic Magnesium

Vaccination

VACCINATED persons, when exposed to the same risk of taking smallpox as unvaccinated persons, are attacked at a lower rate, and those who are attacked die at a lower rate than persons who have not been vaccinated No one who is acquainted with the direct and collateral evidence doubts that this is a generally true proposition, unless they are on *a priori* grounds convinced that vaccination must be nonsense As Prof Major Greenwood pointed out to the Royal Statistical Society on Feb 18, direct numerical evidence of the lower attack and lower fatality rates of vaccinated persons has been obtained whenever the distinction between vaccinated and unvaccinated has been recorded Recent advances in understanding have all confirmed our belief in the efficacy of vaccination as an individual prophylactic

Jenner thought that cow pox (vaccinia) and smallpox (variola) were distinct diseases, and such has been the uncritical general opinion almost to the present day It was accepted on all hands that an attack of smallpox, either naturally contracted or imposed by deliberate inoculation, was a fairly efficient protection against a second attack But it naturally seemed a little strange that protection could be obtained by an attack of another disease, and there were no clear analogies of this non-specific immunisation measles protected against measles, chicken pox against chicken pox, distemper against distemper , and it is not altogether surprising that acute men like Charles Creighton came to the conclusion that vaccination was quackery

Was Jenner right, however, in his original interpretation of his facts ? The modern view is that he was not, and that what he called cow pox on the cows' udders and dairymaids' hands was in fact smallpox No one now knows exactly what cow pox was or is the disease, if it ever had an independent existence, is almost or quite unknown nowadays Equally, the original sources of the strains of virus used for making vaccine lymph for human use are not always known, or at any rate the information is not available for the interested public In some instances, however, they are admittedly derived from human variola, and it seems most likely that all or nearly all human vaccination is actually performed with smallpox material cultivated in the skins of calves, sheep, rabbits, monkeys, or some combination of these and other animals In short, vaccination to-day is essentially the same as the inoculation of the eighteenth century we still protect against small-

pox by inoculating with smallpox, only we use a milder strain of virus, which has to a large extent lost its particular capacity to cause serious illness and death in man by being adapted to grow in other species of animals There is, therefore, nothing surprising or repugnant to general principles in the fact that 'vaccinia' protects against variola Their identity has been fully confirmed by the intensive studies and animal experiments made in recent years by Gordon, Tulloch, and others

Though, however, the efficacy of vaccination in protecting the individual is beyond question, it is by no means so certain that the great diminution of smallpox in western Europe in the closing years of the nineteenth and early years of the present century was due to wholesale vaccination, or that its communal efficacy is such that it may rightly be imposed upon reluctant people It seems fairly certain that compulsory vaccination in infancy, followed by periodical re-vaccinations in later life, if rigidly enforced with no exceptions of any kind, would obliterate smallpox in the inhabitants of Great Britain and render occasional importations from abroad innocuous But would it be worth while? The experience of Leicester shows that the frequent introduction of smallpox into a town where infant vaccination has been systematically neglected does not, in fact, lead to widespread and murderous epidemics It has also to be recognised that, on the modern standard of healthiness, vaccination is not a wholly negligible event It often leads to distasteful malaise, rarely to serious illness, very occasionally to death, and something of this price would doubtless have to be paid for complete security against smallpox The type, too, of smallpox which has been prevalent in Great Britain during the last few years (and which is possibly the indigenous English form) is quite a mild disease, not much worse than chicken-pox or even vaccinia This naturally makes people think more lightly of the disease than they used to, though it is obviously unwise to be sure that the mildness of type will never evolve into the form which caused the horrors of the eighteenth century, and still exists in the East and elsewhere, and is always liable to be brought into Great Britain

With such a conflict of considerations, public health administration plainly has a difficult problem to solve To abandon vaccination would save a few lives and a good deal of inconvenience, and it might lead to no harm on the other hand, it might result in serious disaster The majority will probably agree with those who prefer to be on the safe side

Hydrodynamics.

(1) *Grundlagen der Hydromechanik* Von Prof Leon Lichtenstein (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, herausgegeben von R Courant, Band 30) Pp xvi + 506 (Berlin Julius Springer, 1929) 38 gold marks

(2) *Leçons sur l'hydrodynamique* Par Prof Henri Villat (Chaire de mécanique des fluides et applications, Fondation du sous secrétariat d'État de l'aéronautique) Pp viii + 296 (Paris Gauthier Villars et Cie, 1929) 50 francs

(3) *Hydro- und Aeromechanik nach Vorlesungen von L Prandtl* Von Dr O Tietjens Band 1 *Gleichgewicht und reibungslose Bewegung* Pp viii + 238 (Berlin Julius Springer, 1929) 15 gold marks

(1) THESE three books all deal with hydrodynamics, but differ widely in scope, and appeal almost to different types of mind Prof Lichtenstein, well known for his elegant investigations of some special problems, here undertakes a systematic survey of the science from a strictly logical point of view, incorporating an account of the researches on the existence-theorems of the subject on which he has been engaged for a number of years He submits to a rigorous scrutiny the various conceptions which lie at the base of the science, as well as the assumptions which have been made implicitly in its development This task is here essayed for the first time in the present connexion The classical writers and their followers have been accustomed to pass lightly over such matters and to be guided (often unconsciously) by physical intuitions rather than logical deductions In this they were entirely justified, for it is hard to see how they could otherwise have got on with their own primary business, to construct a mathematical scheme which should represent as well as might be the processes of natural phenomena But at length the pure mathematician comes into the field He is attracted by the interest and beauty of the mathematical structure which the classical writers have by degrees built up, but his keen logical eye detects flaws here and there, he is impelled to strive after precision where he finds vagueness in fundamental conceptions, and to supply *lacunæ* in the logical processes

This is the task to which Prof Lichtenstein has set himself in this book, which, he tells us, is the outcome of some six years' meditation It may be said at once that the result is worthy of the pains

bestowed The work is admirably arranged and lucidly written The arguments are of course highly technical and intricate, and not always easy to follow by a reader inexpert in the more abstruse departments of modern mathematics The easy-going 'intuitional' mathematician may be dismayed at the outset by a recital of definitions from the 'Mengenlehre', and may be astonished to find what a number of unsuspected assumptions he is in the habit of making when he talks lightly of a 'curve' or a 'surface', or even of a 'space' When he proceeds further he will find that the statements of theorems which have become familiar and almost obvious to himself are hedged about with a multitude of tedious limitations and restrictions But all this is no new phenomenon in the development of science, and is indeed of the nature of the case

One or two examples may be given of the kind of question here discussed Thus, suppose we have an unlimited mass of frictionless incompressible fluid, not necessarily homogeneous, at rest at infinity, and that it is in a prescribed state of continuous motion at a given instant t_0 The question is, Do the differential equations of hydrodynamics, without any appeal to experience, logically determine a definite and continuous state of motion for any subsequent instant t? The intuitionist has no hesitation about the answer, he is by nature a determinist, and is confident that his equations are adequate and consistent But it must be confessed that his faith rests on physical prepossessions rather than on strict deduction If he turns to the final chapter of the book, which is devoted to existence theorems of this and other more complicated types, he will find what a long and intricate process of reasoning is needed to establish the conclusion

Again, suppose that the mathematical equations involve some parameter which admits of continuous variation Does the motion which is governed by these equations vary in a continuous manner with the parameter? This question is raised, but not discussed in detail The author, indeed, states frankly that many questions still remain to be examined from the point of view of his treatise The case of compressible fluids, where mathematical discoveries of interest to the physicist are not impossible, is left aside The problems suggested by the theory of viscosity are in like case

Enough has perhaps been said to indicate the special character of the book But it should be added that the expositions of classical theory which are given incidentally as a text are extremely elegant, and are worthy of some attention from readers who may not wish to embark on the study of the intricate commentary

(2) The treatise of M Villat is based on a course of lectures given at the Sorbonne It deals with the various efforts which have been made to construct a strictly mathematical theory of the resistance which a fluid opposes to the motion of bodies through it The first to be considered is the two-dimensional theory of discontinuous motions originated by Helmholtz and developed by Kirchhoff, Rayleigh, and others The author discusses in detail the case of the flat lamina, following a method due to Levi Civita, and obtains of course the well known result of Rayleigh The theory in question had at one time a great fascination for mathematicians, on account of the power and elegance of its methods It will always retain a place in mathematical expositions, but its practical deficiencies have long been recognised It does not give the actual distribution of pressure over the faces of the lamina, and fails altogether to account for the suction in the rear to which most of the resistance is due

The rest of the work is devoted to an exposition of the interesting theory of Oseen This is a theory of slow motions, and only takes partial account of the inertia of the fluid On the other hand, viscosity is not ignored, though it is assumed to be infinitesimal More precisely, the investigation seeks to determine a priori the form which a solution of a particular problem might be expected to assume in the limit when $\mu \to 0$ Two special cases due to M Zeilon are here worked out, namely, the case of a hemisphere advancing with its flat, or with its curved surface in advance Here also there is a sharp discrepancy between the theory and experiment

M Villat's exposition is exceedingly clear, and is adapted to students who come to the subject with no great previous knowledge beyond the range of ordinary pure mathematics The various ancillary theories are discussed as occasion arises Thus we find a preliminary sketch of the theory of complex functions and conformal representation When Oseen's theory is approached we find a chapter on the theory of the potential M Zeilon's problems of the hemisphere, again, are prefaced by a brief account of zonal harmonics The book is thus logically complete, but it remains, alas, true that the student who wishes to get a physical insight into the mechanism of fluid resistance must have recourse to the experimental literature of the subject, with at present only imperfect guidance from pure theory

(3) In the third book on our list we come in contact with reality It is based on lectures given at Göttingen by Prof Prandtl, and is issued under his supervision and with his occasional collaboration It is expressly designed to form an elementary introduction to the classical hydrodynamics so far as this bears on practical questions The student is led on by easy stages from the fundamental conceptions to the final mathematical scheme The explanations are full and lucid, and illuminated by occasional touches which betray the master hand A word must be said in praise of the abundant diagrams, which though small in scale are exquisitely clear The volume is to be followed by another dealing more particularly with technical applications, including (it is to be presumed) the problems of aviation Already in the present volume a number of technical questions are touched upon by way of illustration Thus in the section on hydrostatics there is an interesting account of the statics of the atmosphere, the influence of moisture, the formation of clouds, and the behaviour of a balloon under various conditions At a later stage we have discussions on the efflux of gases, the flow round an aerofoil, and the trail of vortices shed by a screw propeller

The matter and style of the book are to be warmly commended, and not least to students whose approach to the subject has been hitherto mainly from the analytical side

HORACE LAMB

From Thales to Einstein

Two Thousand Years of Science the Wonders of Nature and their Discoverers By Prof R J Harvey Gibson Pp vii + 362 (London A and C Black, Ltd , 1929) 12*s* 6*d* net

THE lack of scientific knowledge among the general public is universally recognised and deplored in the world of science We may hope that the defect will be remedied in the next few generations, since science is now a part of all secondary school education and will doubtless permeate the elementary schools before many years are past At the moment, however, there is a very real need for books which will give the layman some acquaintance with science and its development without entering too deeply into points of technical detail Prof Harvey Gibson's book is a valiant effort to give a popular résumé of the history of science from the earliest times to the present day, and as such commands at least our admiration for its courage, even if we cannot unreservedly award it our full approval on all points

It is a melancholy task to review a book the author of which never lived to see it published Prof Harvey-Gibson, after a life whole-heartedly devoted to the pursuit of science and the propagation of scientific knowledge, unhappily died while the present volume was still in the early stages of its passage through the press Mr A W Titherley, however, upon whom fell the duty of bringing it into final shape, has striven to follow the spirit and intention of the author, and there is small likelihood that Prof Harvey Gibson would have made any extensive alterations

In his preface, the author says that he has tried to write a book of reasonable size which will give the general reader a sketch of the growth of science from early times, and in which he will also find an explanation, written in popular terms, of some of the principal subjects at present occupying the minds of scientific men It is an ambitious project, and the two aims are fulfilled with varying degrees of success To write a history of science in the small compass of three hundred and fifty pages is an undertaking before which the boldest might hesitate, and in point of fact Prof Harvey Gibson has not accomplished it What he has done is to give a brief account of some outstanding figures of science up to the eighteenth century, followed by a description of subsequent advances in physics, chemistry, biology, geology, and astronomy There is consequently a lack of balance about the book as a whole, the earlier sections being too short and disjointed to have any great value Thus Greek science is dismissed in twelve pages, while Roman science is omitted completely except for three incidental references to Pliny Arabian science is described in four short paragraphs, and even these contain such surprising errors as that the introduction of Arabic numerals was due to 'Ben Musa', presumably Al Khwarizmi

The first seventy pages of the book, dealing with science up to the eighteenth century, fall far short of the standard of the remainder They might profitably have been replaced by a general essay on classical and medieval science, which would have formed a much better introduction to the later periods than the somewhat staccato effect of the treatment adopted It is, indeed, abundantly clear that Prof Harvey Gibson did not feel at home in the earlier ages of science, but was anxious to arrive as quickly as possible to the more familiar and more fruitful later centuries With this transition, the level of the book rises steeply, the

material is selected with care and sound judgement, and the story runs smoothly and well. Particularly clearly in the biological sections, but adequately in all, the author brings out the essential features and shows the gradual unfolding of the flowers of science.

The twin aims of the book are never overlooked; Prof. Harvey Gibson was determined that the reader should not merely know about a discovery, but that he should actually understand the discovery. In some cases the explanation is necessarily compressed so much that the non-scientific reader will find the going hard, but, on the whole, the author has successfully anticipated and provided for the difficulties that inevitably arise. Any intelligent layman should be able to follow the arguments without undue mental strain, and it was for him that the book was written. Men of science may be expected to know something of the history of science in general and of their own branches of it, but if they wish to supplement their knowledge without devoting too much attention to minutiæ, they will find Prof. Harvey-Gibson an entertaining and well informed guide. It remains to be said that the book is well printed, but that the illustrations might have been more numerous and of better quality. E. J. H.

Photochemistry

Photo Processes in Gaseous and Liquid Systems. By Dr. R. O. Griffith and Dr. A. McKeown. (Textbooks of Physical Chemistry.) Pp. viii + 691. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 25s. net.

IT has been stated, possibly with truth, that any investigations performed by chemists which prove to be of more than passing interest are rapidly assimilated by and incorporated in physics. This stage appears to have been reached in the subject of photochemistry, ably dealt with by Drs. R. O. Griffith and A. McKeown in "Photo Processes in Gaseous and Liquid Systems", published in the well known Longmans Green series of text books on physical chemistry, edited for so long by the late Sir William Ramsay, and now under the genial direction of Prof. F. G. Donnan.

It is clear that, in order to gain an insight into the reasons why absorbed light causes an atom or molecule to become chemically reactive, it is necessary to find out what is the fate of the absorbed energy and what changes in the molecular electronic, vibrational or rotational energies take place as a result of such absorption, and in what manner these may be interdependent, before one can state definitely that chemical reactivity is imparted by such and such a change in the molecular system. This the authors have clearly recognised, for they have devoted no less than half the volume, which contains six hundred and eighty pages, to such considerations. This section of the book is conveniently divided into five chapters, commencing with a classification of spectra, the Bohr theory of spectral lines, the spectra of atoms including transition probabilities and lives of excited and metastable atoms.

Chapter iv. is devoted to the more complex case of molecular spectra, which introduces naturally the subject of fluorescence. It is only natural that in such a rapidly growing subject any book written will be 'dated' at the time of publication. Whilst the authors have kept well abreast of the times in many sections of the subject matter in this portion of the volume, in others information anticipated in a volume published in 1929 is not to be found. Thus the section on rotational and vibrational molecular spectra might well have been amplified. The statement (p. 33) that "the infra red bands of carbon monoxide and of carbon dioxide are not capable of complete resolution" must certainly be regarded as somewhat sweeping. Whilst on page 54 some space is devoted to the Compton effect as evidence for the existence of the light quant or photon, it is somewhat curious that the analogous effect discovered by Raman, which has proved of such value in the determination of infra-red molecular spectra, is not even mentioned, although it is now common practice to employ the Raman effect for the identification of lines in the infra red molecular spectrum.

In discussing the optical convergence limits for the diatomic gases such as nitrogen, oxygen, and the halogens, with the object of determining the heats of dissociation, it is somewhat unfortunate, on account of the frequency with which they are used in thermochemical calculation, that in both nitrogen and oxygen figures more recent than 1926 have not been employed; the values given are certainly much too high. The chapters on fluorescence and chemiluminescence are full of interesting information; in the latter the oxidation of dyestuffs such as safranin by ozone might have been included just for the sake of its beauty and suitability for lecture demonstration purposes.

In the second portion of the book, two chapters are devoted to the Stark Einstein law of photochemical equivalence, the experimental confirmation of which was commenced by Warburg; one

to the still mysterious chlorine-hydrogen and chlorine-carbon monoxide reactions, and one to the important phenomenon of photosensitisation The last chapter includes a discussion on the temperature coefficient of photochemical reactions and phenomena resulting from the intrusion of catalysts in photochemical reactions It is interesting to note (p 556) that the authors do not favour the concept of an excited chlorine atom as being the link in the atom chain mechanism so long sought for in the hydrogen chlorine combination, although recent work from Semenoff's laboratory lends additional support to this view The treatment, however, in this portion of the book is very fair to the diverse views which have been expressed, and the criticism which is presented from time to time by the authors is both pertinent and stimulating The authors are to be congratulated on writing what may well be considered the standard text-book in this growing subject

ERIC K RIDEAL

Our Bookshelf.

The Glorious Oyster his History in Rome and in Britain, his Anatomy and Reproduction, how to cook him, and what various Writers and Poets have written in his Praise, collected together as an Acknowledgment of the Supreme Pleasure he has given to all Persons of Taste since Roman Times By Hector Bolitho With certain Chapters edited by Maurice Burton Pp x + 203 (London and New York Alfred A Knopf, 1929) 6s

THIS small book is " written merely as a record of those stories of the oyster of which the author has read, brought together as a tribute to *his* (the oyster's) importance ", and in fulfilment of a long standing vow to write such a book The author's confessions provide a key to the product In historical quotations on the oyster in Rome and Britain (many culled from Philpots, " Oysters and All About Them "), in references to curious habits and an anthology, the author finds a congenial topic, and has collected within a small compass a number of stories and references likely to be of interest to those readers who browse, to some who read lightly, certainly to those who have an affection for the oyster, or who want to find one of the less well-known stories The subject, however, is not treated exhaustively or seriously In an interesting quotation dated 1859 (occupying thirteen pages, and from " All the Year Round ", edited by Charles Dickens) it is recorded that 800 oysters were taken in one dredge haul off Whitstable, where an equivalent catch of all sizes nowadays would probably be a good one if twenty were taken

The author is, unfortunately, not successful in his treatment of reproduction, enemies, and cultivation, in spite of the fact that contributions to these subjects were made by Mr Burton It is apparently a very difficult matter for a (presumed) layman to write on a scientific subject even when provided with the subject matter For example, he writes " As time proceeds, each of the embryos constituting the black spat develops a crown of protoplasmic hairs or cilia and becomes known technically as a ' trochosphere ' larva " The author is amusingly unaware that he is describing the development of the oyster backwards The fall of spat is stated to occur usually in May ! A single oyster is quoted as producing from 300,000 to 60,000,000 eggs in a sentence sandwiched between two others referring to the European oyster It is stated that ' hockling ' is a prevalent and familiar disease, that the mantle is a tough fleshy plate of tissue, that oysters cannot live in water which contains less than three per cent of salt, while a native oyster is still believed to be " one which is or has been bred on or near the Thames Estuary " After quoting Goldsmith on oysters, the author states ' This quotation illustrates the ignorance concerning oysters existing as recently as when Goldsmith was alive " J H O

Thermodynamik die Lehre von den Kreisprozessen der physikalischen und chemischen Veränderungen und Gleichgewichten, eine Hinführung zu den thermodynamischen Problemen unserer Kraft- und Stoffwirtschaft Von Prof Dr W Schottky In Gemeinschaft mit Dr H Ulich und Dr C Wagner Pp xxv + 619 (Berlin Julius Springer, 1929) 56 gold marks

THIS is an interesting and important book, of which at least parts will be of use to all teachers of thermo dynamics The fundamental principles of the subject are dealt with at considerable length, and difficulties are not glossed over but fully discussed

An important aim of the book is to retain the advantages of the analytical method of Clausius-Gibbs-Planck while avoiding the possible obscurity of the characteristic functions, and to retain the close touch with experimentally measured quantities of the cycle method of Helmholtz-van 't Hoff-Nernst while avoiding its clumsiness New coefficients, called heat and work coefficients, are introduced which have a close and obvious connexion with the measured quantities of heat and work At the same time, these coefficients are shown to depend only on the state of the system and their relation to the older characteristic functions is worked out Although at a first reading the new notation is rather confusing, it is an advantage where possible to have experimentally measured quantities in the equations In this connexion reference must be made to the large amount of information concerning the relations between experimental quantities that, with the new notation, is compressed into the two small tables on pp 77 and 78 Whether the new method will appeal to students more than the old can only be found by trial

Another important point is the development of the ideas of Gibbs on the components of a system in a natural and helpful way by the introduction of the conception of resistant groups The appli-

cations of thermodynamics to homogeneous and heterogeneous chemical systems are considered at length

From the point of view of the teacher who decides to use the new method, it would have been better to arrange the book so that the possibilities of classical thermodynamics were more fully exploited before the introduction of the Nernst heat theorem Also the eighteen numerical applications would be better in the main text, and considerably increased

The History of British Civilization By Dr Esmé Wingfield Stratford Second edition, revised Pp xix + 1332 (London George Routledge and Sons, Ltd, 1930) 15s net

IT is very satisfactory to see that Dr Wingfield Stratford's work, reviewed in NATURE of June 8, 1929, p 863, has already reached a second edition in one volume The price of the first edition in two volumes was the only obstacle to the wide popularity of the book, the price of the second removes that difficulty, for no one can 'boggle' at 15s for 1300 large and well printed pages

The book is certainly a godsend, for repeated trials on the average intelligent person have convinced us that it has just the elements needed for success—a very wide reading on the part of the author, a generous and impartial spirit, a lively style, a strong personal interest, and a burning enthusiasm for his country It is not an elementary history for schools, it is not a scientific history, based on documents and adding to our knowledge, but it is a real book, adding to our interest and bringing together, from a new and personal point of view, a multitude of facts and personalities of which most people have some vague and often disconnected knowledge

When one considers the vast importance of the subject and its growing complexity, this is great service to the public, and one should be duly grateful to Dr Wingfield-Stratford for having done it so zealously It may be confidently expected that this book will attain to late editions, and, if so, he may find opportunities to make good some of the defects we pointed out in an earlier notice This edition is practically a reprint of the first F S M

Hindu Exogamy By S V Karandikar (University of Bombay Publication) Pp xv + 308 (Bombay D B Taraporevala, Sons and Co, 1929) 6 rupees

IN attempting to formulate a theory of Hindu exogamy, Mr Karandikar has attacked a subject of considerable intricacy, and if his book is difficult the fault is not to be attributed to the author He seeks to extract the evidence for exogamy from the earliest Sanskrit literature and to trace its history and development through the later documents, while at the same time comparing or contrasting it with the practice in Indian culture Owing to the general dissociation of the study of Sanskrit literature from anthropological studies, the subject is not one which hitherto has been attacked on these lines It would appear that among the Aryan invaders, exogamy was not practised Indeed, the union of close kin was encouraged The present exogamy of the Indo Aryans is derived from the *gotra*—sept or clan—a word which occurs a few times only in the Rig-Veda On the other hand, there appears to have been a form of *sapinda* exogamy based upon the generations on both the father's and the mother's side Mr Karandikar has traced the development of these forms of exogamy from early times and shows how, by a process of admixture and borrowing as between Aryan and Dravidian stocks, the forms of exogamy as at present practised in India have come about He concludes with some considerations of the eugenic aspect of the practice on the population of India

Bandenspektren auf experimenteller Grundlage Von Dr Richard Ruedy (Sammlung Vieweg, Hefte 101 102) Pp vi + 124 (Braunschweig Friedr Vieweg und Sohn A G, 1930) 9 60 gold marks

THIS famous series of monographs has now added to its number an excellent little volume on band spectra by Dr Richard Ruedy of Toronto This appears at a time when rapid progress is being made both on the theoretical side by Hund, Mulliken, and others, and on the experimental side by a large number of workers in many countries The foundations of the subject are, however, sufficiently well established to justify a volume of this scope, and it should prove a trustworthy and valuable introduction to the whole subject of electronic band spectra, especially for those who have not previously had any specialised acquaintance with the subject

This book to some extent covers the same ground as Mecke's article in the 'Handbuch der Physik", vol 21, but there is ample scope for several presentations of the subject by men who can write authoritatively Dr Ruedy has managed to compress into moderate space a very lucid and attractively arranged account of the basis of this difficult subject

Physikalische Beiträge zur Radium emanations therapie Von Heinrich Mache und Stefan Meyer (Abhandlungen aus dem Gesamtgebiete der Hygiene, herausgegeben von Prof Dr R Grassberger, Heft 5) Pp 32 (Leipzig und Wien Franz Deuticke, 1929) 2 40 gold marks

IT is commonly supposed that thermal waters possessing radioactive emanations exert therapeutic action due to the emanations, but definite data concerning this are difficult to find. The authors of the two papers contained in this memoir give the results of investigations on the entrance into the body of the radioactive emanations of the Gastein thermal waters by bathing, by drinking, and by breathing air containing them By drinking and by breathing, the emanations rapidly enter the blood, but are quickly eliminated, though it is questionable if the emanations can enter through the skin by bathing Quantitative data are given of the amount of the emanations found in the blood and of the rates of accumulation and elimination of the emanations

Letters to the Editor.

Curling.

WE should like to direct attention to the question of what can be learnt about ice friction from the well-known behaviour of a curling stone

A stone laid tee high has a run of 42 yards It has spin (called handle), which remains almost constant until near the end of the run The total lateral divergence of the stone, from the straight line on which it is laid by the player, is called the borrow Clockwise spin (in handle) causes divergence to the right, the opposite spin (out handle) causes divergence to the left Spin is necessary, because a stone laid without spin is at the mercy of any slight irregularity in the ice which may catch one side of it Ordinarily, the spin is between 3 and 5 complete turns in the run of 42 yards Between these limits the borrow is not much affected by the amount of the spin, probably it is affected a little, increasing slightly with increased spin But a substantial increase of the spin beyond this range decreases the borrow, and

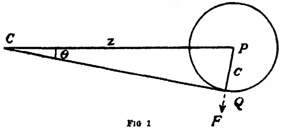

FIG 1

by giving a very heavy spin a nearly straight path can be obtained Sweeping in front of a stone, which on good dry ice reduces friction, at the same time delays or reduces the bending of the path

Sir Gilbert Walker has remarked that the direction of the borrow requires that the friction at the back edge of the cup, on which the stone runs, should be greater than at the front edge, and that, in consequence of retardation, the pressure between the stone and the ice is greater in front than behind But we have not been able to hear of any attempt to consider the borrow quantitatively The following calculation for a simple case will show the way in which we have attacked the problem

Suppose the total friction to be constant, and applied in the way most favourable to curvature of the path, and let us deal only with the first 40 yards of the run By the omission of the last two yards we avoid complications introduced at the very end of the run, and this is found, in our calculation, to be sufficient to provide that we are dealing with a portion of the run in which the angles involved are small angles the squares of which are negligible

Let P be any point in the first 40 yards of the path of the centre of a stone laid tee high Let C be the instantaneous centre of the motion, and Q the point of contact of a tangent drawn from C to the cup Then PCQ is a small angle, θ We assume that the friction at any point acts in the direction opposite to that in which the point is moving, but we do not know how it is distributed round the cup Let us take the extreme case in which it is concentrated into a single force, F, at Q, in the direction of PQ We will assume this force to be constant We write F for $F\cos\theta$, and the force along the normal to the path is $F\sin\theta$, or $F\frac{c}{z}$, where c is the radius of the cup, and z is written for CP Let M be the mass of the stone, τ the whole time of the run, and l the whole length, s the length of the path measured backwards from the tee up to P, ψ the inclination of the tangent at P to the line on which the stone was laid, y the distance of P from this line, ρ the radius of curvature, v the velocity of the centre of the stone, f the tangential component of the retardation, and ω the angular velocity, which must be constant within our range Then the following equations seem to be nearly correct

$$Mf=F, \quad l=\tfrac{1}{2}f\tau^2, \quad v^2=2fs, \quad \frac{v^2}{\rho}=f\frac{c}{z}, \quad v=z\omega,$$

$$\frac{1}{\rho}=-\frac{d\psi}{ds}, \quad -\frac{dy}{ds}=\sin\psi$$

Thus we get

$$-\frac{d\psi}{ds}=\frac{fc\omega}{v^3}=\tfrac{1}{4}c\omega\tau l^{-\frac{1}{2}}s^{-\frac{3}{2}},$$

and, by integration,

$$\psi=\tfrac{1}{2}c\omega\tau l^{-\frac{1}{2}}(s^{-\frac{1}{2}}-l^{-\frac{1}{2}}),$$

and writing $\sin\psi$, or $-\frac{dy}{ds}$, for the small angle ψ, and integrating again,

$$y=\tfrac{1}{2}c\omega\tau l^{-1}(l^{\frac{1}{2}}-s^{\frac{1}{2}})^2$$

With a cup of $4\frac{1}{2}$ inches diameter, and a spin of 5 turns in the length of the run, the value of $\frac{1}{2}c\omega\tau l^{-1}$ is about 0 025 Thus the value of y at a point 2 yards short of the tee is 1 ft 11 in (At this point θ and ψ are about 0 1)

This is a disconcerting result No reasonable correction of the point from which s and l are taken to be measured alters the general character of it The calculated borrow might perhaps be accepted for average conditions, but it is much too small to admit allowance for variation of the data To account for the facts, it seems to be necessary to suppose that increased spin tends (in some way not explained) to equalise the friction in front and behind, and thus counteract the effect of the increased value of ω But by putting all the friction behind, with a spin of 5 turns, we have not left room for this, nor for the occasional occurrence of borrow of exceptional magnitude

There remains the question whether it is approximately correct to take the total friction to be constant during the run We know its average value, the question is whether it increases to a value substantially above the average as the velocity decreases In several successive years, so far as we have had occasional opportunities, we have tried to test this But our results have not shown this variation, indeed, our records have a slight tendency to show a little decrease of friction at the point at which increase is most wanted We began by using stop watches, but eventually we had a suitable electric chronograph, and stretched threads across the ice, the slightest twitch of which made an electric contact Thus we have some fairly accurate records

We have also used a dynamometer to test the relation between total friction and pressure For various reasons this could not be used so as to give very accurate results, but it showed that if a stone was loaded so as to increase the pressure by varying amounts up to 40 per cent, the total friction was nearly constant Doubled pressure gave a considerable increase of friction A consistent variation of

10 per cent would not have escaped notice The friction thus measured, when a stone was towed at a foot's pace, agreed roughly with that shown in an ordinary run of a stone

It seems clear that we have failed to take account of some important feature of the motion What is it ?

Gaseous Combustion

I AM greatly indebted to Prof Bone for the very clear exposition of his views in the issue of NATURE for Feb 22 I think, however, that a serious mis understanding has arisen which I should like to try to make clear

In the letter in NATURE for Jan 25 from Mr Davies and myself, it was stated that our new experiments suggested the analysis of the overall process of com bustion into two broad stages

(1) The combination (and of course the main) stage, resulting in the formation of molecules of carbon dioxide and water of abnormal structure, during which the energy released is $H - x$, where H is the heat of combustion

(2) The passage of these molecules of abnormal structure into normal molecules during which energy x is released (While x cannot be a large proportion of H, the platinum wire experiments mentioned in our letter suggest that it is of appreciable magnitude)

The misunderstanding mainly arises, I think, in the matter of time scale The second stage—if the suggested analysis is to explain our experiments—must be regarded as being one of extraordinarily long duration when combustion takes place in the gaseous phase As indicated in our letter, we appear to have traced its existence for so long as 14 seconds after maximum pressure in an explosion, and we have little doubt that we could trace it for a much longer time with new apparatus

Assuming the correctness of this view, it will be clear that in ordinary explosion experiments, in which measurements are rarely, if ever, made later than one second after maximum pressure, this stage, so very slowly does it progress, may for many purposes be disregarded and the explosion regarded as one in which energy amounting to $H - x$ approximately is released It is, for example, disregarded in this manner in the coal gas explosion experiments men tioned by Prof Bone, from which I estimated that about 10 per cent of the gas is unburnt at maximum pressure, for the method adopted was roughly that of comparing the energy at the moment of maximum temperature in a weak mixture explosion with that remaining in an exploded strong mixture after it had cooled to the maximum temperature of the weak mixture, and the cooling to this temperature took only about $\frac{1}{4}$ sec Thus the estimate of 10 per cent unburnt gas (which should now be amended to the slightly different value 10 $H/(H - x)$ per cent) derived from these experiments refers only to incompleteness of the first stage The experiments further appear to indicate that burning in the weak mixture is also complete in this sense in about $\frac{1}{4}$ sec after maximum pressure (*Proc Roy Soc*, vol 98, p 313)

While Prof Bone is somewhat doubtful as to the duration of what we have termed the second stage in the overall process of combustion, I think I am right in my interpretation of his letter in assuming that the main difference of opinion between us is in regard to the way in which this 10 per cent (or rather 10 $H/(H - x)$ per cent) is to be accounted for My view in regard to this is unchanged, I believe that it is to be accounted for in terms of uncombined gas Prof Bone believes that it is to be explained in terms of excess energy concentrated in the vibratory and rotational degrees of freedom of the freshly formed molecules I fully admit that, in the absence of chemical analysis, my view must remain a hypothesis, but I prefer it to his view for the reason he mentions, namely, that I think par titioning at explosion temperatures must be very rapid, and also because my experiments indicate that the radiation at the maximum temperature in a weak or medium mixture is very little greater than that from a strong mixture when it has cooled to this temperature Such small difference as there is may be readily explained in terms of the greater tem perature variation in exploded gases at the moment of maximum temperature than some time later, and also of the higher transparency of the gases at that time (*Phil Trans* A, vol 211, pp 386 and 398, and *Proc Roy Soc*, A, vol 98, pp 189 and 195) Further more, I find less difficulty than ever in believing in the reality of incomplete combination at maximum pressure in ordinary explosions since Prof Bone has published his analyses of the cold products of dry carbon monoxide mixture explosions He shows that in these very stubborn mixtures there is a large pro portion of carbon monoxide in the products after ex plosion, although the flame during the explosion period had completely traversed the mixtures and the time interval during which combination could take place was very much longer than the interval from ignition to maximum pressure in ordinary explosions

The main object of our letter published in NATURE for Jan 25 was to suggest that what we have called the long drawn out second stage in the overall process of combustion is a possible explanation of our lumin osity and platinum wire measurements As already stated, we found that in a large explosion vessel (18 inch sphere) silver plated so as to arrange for as slow cooling as possible, the luminosity in a 30 per cent moist carbon monoxide–air mixture at 3 atmospheres density remained visible to the eye for at least 14 sec after maximum pressure, that is, until the temperature had fallen to about 300° C I believe Prof Bone has a high pressure explosion vessel fitted with a quartz window, and it would be of great interest if he could indicate the duration of luminosity after maximum pressure in a high pressure explosion and also give an estimate of the temperature at which luminosity disappears If, as seems reasonable to suppose, the second stage is speeded up in a high density mixture, the temperature at which luminosity ceases to be visible to the eye should be higher than 300° C

If the second stage can be shown conclusively to exist, it is of interest to note that an internal com bustion engine exhausts the working fluid with its carbon dioxide and water molecules in the abnormal condition, and, if x is appreciable, an appreciable amount of energy is thereby wasted A window fitted to the exhaust pipe of a gas engine shows that the ex haust gases (temp 500° C 600° C) are luminous, though chemical analysis fails to detect uncombined gas

Exceedingly interesting information can be collected from the literature of the internal combustion engine in this connexion For example, Hopkinson, by means of an exhaust gas calorimeter, found in the exhaust gases actually more heat that he deduced from the temperature (as inferred from the pressure) of the working fluid in the cylinder at the end of the explosion-expansion stroke, in spite of the fact that the opinion is firmly held that as much as 10 per cent of the heat of combustion of the charge is lost to the cylinder

walls and the exhaust valve during the exhaust stroke, and has therefore been extracted from the working fluid before it reaches the calorimeter (Scientific Papers, pp 272 and 288)

This would, of course, yield a very high value for x—much higher than I should have thought possible It is right, however, to add that although Hopkinson's experiments relate to the same engine and are given in the same paper, he does not appear to have correlated the two sets of figures But even so, after making large allowance for possible experimental error, we are still left with a value for x which suggests its very real practical importance

Australian Origin of Red Rain in New Zealand

WE have recently had two striking examples of the manner in which the influence of a continent may extend, in ways which might easily be overlooked, to enormous distances round about it It is well known that in dry years large quantities of smoke from bush fires in Australia are carried by the south east monsoon over the East Indian Archipelago On Oct 25 and 26, 1929, however, dense haze, which can have had none other than an Australian origin, was seen at the Island of Niue in lat 19° S, long 170° W, 2300 miles distant from Australia The meteorological observor, Mr J P McMahon-Box, reports that "A strange smoky haze enveloped the whole Island on the 25th and 26th It came up about midnight on the 24th to 25th, apparently from the south west, in which direction it was densest Visibility was very poor indeed It disappeared during the night of the 26th to 27th We experienced a couple of thunderstorms during the period of the haze "

On reference to the weather charts, it is found that on the morning of Oct 22 a rather intense anticyclone was centred just west of Tasmania, while a deep cyclone had developed in the Tasman Sea Strong south west or southerly winds were blowing over eastern Australia, where there had been little rain It is probable that dense masses of bush fire smoke mixed with fine dust started on the journey to Niue on that day During the following days the cyclone moved eastward, its track curving round to the north of New Zealand At 9 A M (New Zealand time) on Oct 24 its centre was in about 32° S and 178° E, the pressure being below 29 10 inches The strong west to south winds in the north west quadrant of the cyclone made conditions ideal for the transport of dust and smoke from Australia to the Pacific Islands It is worth noting that thunderstorms were reported near the centre of the cyclone on both Oct 22 and 24, when vessels happened to be favourably situated

The second phenomenon was recorded in New Zealand on Nov 27, when copious deposits of red dust, such as is found in the interior of Australia, were brought down by rain over a wide area covering the Marlborough, Nelson, and Taranaki Provinces, and the portion of the Wellington Province lying to the west of the mountain ranges Flowers, washing, motor cars, etc , were stained a pale chocolate colour Many observers noted that the clouds had a reddish brown appearance and some severe thunderstorms occurred Several samples of the dust were sent to the Meteorological Office Another interesting sample was forwarded by Mr A C Jones, the second officer of the M S *Taranaki* This was found adhering to damp structures on the vessel when 190 miles from the Australian coast on Nov 23 The vessel was in dust haze when between the following positions, 39° 43′ S , 151° 4′ E , and 39° 56′ S , 152° 43′ E

On this occasion again the dust was brought to New Zealand by the winds in the north west quadrant of a complicated depression which moved across the Tasman Sea between Nov 23 and 28 This depression was at first of the inverted V type, but afterwards two cyclonic centres developed in the northern portion One of these disappeared, and by Nov 27 a deep cyclone was centred off the south west coast of the Dominion

At Reefton, in the Nelson Province, a slight sediment was left by the rain on Sept 4, 1929

The most notable deposit of dust from Australia on New Zealand occurred, however, on Oct 6–10, 1928, and is described in papers by Dr P Marshall and myself in the *New Zealand Journal of Science and Technology*, vol 10, No 5, pp 291 99, 1929 Following on that occurrence the snow for many miles, probably 200 to 300, along the main ranges of the South Island, was for months stained a pale chocolate colour On Ben Lomond, near Queenstown, in Otago, at the end of October, I found the snow impregnated with the dust in a layer about five inches thick From the amount of snow I was able to carry away in a hand kerchief, more than 4 grams of deposit were collected 200,000 tons is a conservative estimate for the weight of the total deposit on New Zealand in this fall On this occasion, also, thunderstorms were numerous and very violent, and it seems certain that the suspended dust is, in part at least, responsible for their development

It will be seen that dust storms of the nature described may, in the course of time, be responsible for a red sediment of no inconsiderable thickness on the floors of the Tasman Sea and the Pacific Ocean

EDWARD KIDSON

Meteorological Office, Wellington,
Dec 27, 1929

THE sample of red rain dust collected at Ben Lomond, near Queenstown in southern New Zealand, by Dr Kidson, which the Editor has kindly sent me for inspection, agrees in its microscopic characters with falls previously described It contains some coarse quartz grains, doubtless of local origin, but the bulk is a fine clay and silt such as is common on the dry lake beds of the interior of Australia , it contains some diatoms and shreds of algæ, which look like those that grow in the pools in such localities

The red rain that falls in Victoria acts as an indelible stain on fresh paint, and that which fell on Feb 14, 1903, was proved by F Chapman and H J Grayson (*Vict Naturalist*, vol 20, pp 17 32, pl i, ii, 1903) from the diatoms to be derived "from the swamps and salt lakes which fringe the River Murray and its tributaries " and from other rivers in South Australia These authors proved the same origin for some material which I obtained in southern New Zealand, which must have travelled in the air for more than 1000 miles , this record was given in my " Geography of Victoria ", p 264

I cannot determine the diatoms in Dr Kidson's sample , but the character of the material is strikingly like that of the lake plains of Lakes Eyre, Callabonna, etc , in South Australia, and fully supports Mr Kidson's conclusions This record is of interest not only as of another occurrence of his widespread dust distribution, but also from his estimates of its quantity.

This red dust no doubt contributes to the red clay of the deep sea , but that material covers so vast an area, and often lies so far from any likely source of desert supply, that the abysmal red clay is probably

in the main derived from other sources The red clay of the Tasman Sea may be largely composed of this desert dust, and its comparison with that from the central Pacific would be of interest

I have not yet had the opportunity of seeing the recent paper in the *N Z Journal of Science and Technology* referred to by Dr Kidson

Black snow and black rain fall in the south west of Scotland, but when some of this was sent to Glasgow, it was determined by Mr B K N Wyllie as due to particles of slag from the Cumberland iron works (*Scottish Ski Club Magaz*, January 1912, pp 153 5)

J W GREGORY

The Present Status of *Drosophila melanogaster*

DURING more than two decades *Drosophila melanogaster* has occupied a prominent position in connexion with developments in biological theory Its extreme variability was noted in 1906 by Castle, and its peculiarities in this respect were later exploited by Morgan and his associates in a long series of publications On account of the great ease with which this fly can be maintained in cultures and of the short life cycle, it has proved most convenient for genetical investigations Apparently, experimental work excites a disproportionate degree of credence at the present time in connexion with biological theories Experimental work, from the evolutionary point of view at any rate, by itself alone, appears to have a definitely restricted value

It has been known ever since Rosenberg's truly epoch making investigations on the cytology of the hybrid between *Drosera rotundifolia* and *D longifolia* that there are certain cytological characteristics which are of fundamental importance in connexion with the study of hybrids between species Starting with his work on the hybrid between these two species, commonly known as *D obovata*, Rosenberg was led to extend his observations to variable species in Nature, notably the genus *Rosa* as represented by the dog roses of Europe Similar observations have been carried out in my laboratories on other genera of the Rosaceæ, namely, the extremely variable and exceedingly numerous American species of the genus *Cratægus* and of the equally variable American blackberries Further observations carried on in the southern hemisphere in the case of the huge and variable genera *Eucalyptus*, *Acacia*, and *Veronica*, show that this condition is not confined in any way geographically, but is a feature commonly exemplified by large genera This state of variability in large genera was prophetically pointed out, many years ago, by Charles Darwin in the "Origin of Species"

Those species which are the favourite material of genetical experimenters at the present time are species which have all the variability of hybrids This condition has long been recognised in the case of the species of the genus *Œnothera*, which was brought into prominence more than two decades ago by De Vries There are now scarcely any students of the genus who do not admit that its species are very largely contaminated by hybridisation On the botanical side the idea of widespread hybridism in Nature is more and more hospitably received On the zoological side we find, however, a much less degree of cordiality towards this idea It is strongly maintained by many geneticists, for example, that *D. melanogaster* is a good species, and one of the pieces of evidence cited in this connexion is that it does not readily cross with other species of the genus. This turns out to be an untrustworthy criterion, however, because cases are known on the botanical side of experimentally produced hybrids which will not back cross even to their own parents

In 1925 the present writer, in collaboration with Prof G C Hicks, published [1 2 3] a number of observations on the meiotic or maturation division in the male gonads of *D melanogaster* These observations were rendered possible by the development of methods which made it feasible to examine a huge amount of material with a minimum amount of effort The investigations showed clearly that the reduction division in *D melanogaster* presents all the peculiarities of those found in natural or experimentally produced hybrids In 1928, Belar [4] published some photomicrographs which, according to his view, showed the inaccuracy of the observations made by the present writer and Prof Hicks Belar's figures of the division of the primary spermatocytes, however, show a distinct lagging of the chromosomes in the maturation division, which is recognisable by all who are familiar with the cytology of hybrids as a distinct criterion of hybrid origin Very recently Zuitin has published in the *Bulletins* of the Bureau of Genetics of Leningrad (vol 7, 1929) an account of the reduction division in this species His results confirm the accuracy of the observations made by Prof Hicks and the writer, inasmuch as he figures the abnormalities described in our papers published in 1925 He reaches the conclusion, further, that *D melanogaster*, as he puts it, has the cytological abnormalities of "special [obviously the meaning is interspecific] hybrids"

It will be obvious to the reader that *D melanogaster* as an object of genetical investigation must be subject to all the reservations which should be made in the case of the study of hybrids Probably the reluctance of geneticists in general to admit the hybrid origin of *D melanogaster* arises out of the fear lest either the Mendelian hypothesis or the chromosome theory of heredity should be thereby compromised It is also important to note that not only breeding experiments with *D melanogaster* are open to such criticisms as would arise from the hybrid character of the material, but also the investigation of this and other variable species by means of radiations is likewise open to grave question Another prominent weakness of actinic experimentation in connexion with theories of the origin of species is the fact that there is no reason to suppose that such radiations have any important influence in moulding species in Nature

The Water Balance of Plants as a Factor in their Resistance to Insect Pests

As a result of a review of the available evidence with regard to the effect of climatic and soil conditions on the distribution of the *Dysdercus* sp, the hypothesis was put forward by one of us (E P M) in 1925–26 that a disturbed water content, from whatever cause, rendered the cotton plant more susceptible to the attack of sap feeding insect pests, such as various species of thrips. Later it was found that this hypothesis appeared also to hold true in the case of certain sap feeding insect pests of sugar cane, notably the

froghopper *Tomaspis saccharina* Dist So far as cotton is concerned, the hypothesis has since been confirmed by observations made in the field in California

In the autumn of 1926 several extensive tours were made into the cotton growing regions of California, which included not only the well-known Sacramento, San Joaquin, and Imperial Valleys, but also the lesser known Ferris, Coachella, Palo Verde, and Barde Valleys At that time more than 160,000 acres of cotton were growing in California proper, an additional 130,000 acres occurring in Lower California It was then found that thrips (*Heliothrips fasciatus* Perg) attack on Acala cotton invariably followed faulty irrigation practice Thrips were never found in large numbers on plants receiving an optimum water supply It seemed that plants suffering from water shortage were definitely more attractive to the attacking thrips

W B Camp, of the U S Bureau of Plant Industry, working in collaboration with the Department of Agriculture, has been carrying out a series of experiments on these lines for a number of years, and we have reason to believe that this hypothesis is supported and extended by the results of his researches It also receives support from Bedford's observations on thrips (*Heliothrips indicus* Bagnall) attack on Egyptian cotton in the Sudan (*Wellcome Trop Res Lab*, *Khartoum, Ent Sec Bul*, **18**, 1921), though in some respects it would appear to be contradicted by Wardle's observations on *Thrips tabaci* Lind attack on cotton in a Manchester greenhouse (*Ann App Biol*, **14**, 482, 1927 Compare also MacGill, *ibid*, **16**, 288, 1929)

With regard to the sugar cane froghopper (*Tomaspis saccharina* Dist), the hypothesis has also received striking confirmation in practical experiments by Withycombe (*Ann App Biol*, **13**, 64, 1926 *Proc Agric Soc Trinidad and Tobago*, **26**, No 6, 294, 1926) and other workers in the West Indies Increasingly we are led to believe that the hypothesis holds true for a large number, but not all, species of thrips, red spider, etc, as pests of a wide range of food plants Several cases are cited by Lees (*Ann App Biol*, **13**, 506, 1926) in which heavy irrigation and heavy rain fall resulted in increased susceptibility to insect attack, but it is not improbable that, in a number of cases, conditions of physiological drought were present as a result of deficient soil aeration

It seems also that the nitrogen content of the sap is an important factor with regard to susceptibility to attack This has been referred to by Davidson (*Ann App Biol*, **10**, 35, 1923) and by Lees (loc cit) Experiments carried out by one of us (E P M) on the curly top disease of the sugar beet in California, transmitted by the leafhopper *Eutettix tenellus* Bak (results to be published shortly in *Annals of Applied Biology*), point in a similar direction There is, indeed, much evidence available which indicates that a highly nitrogenous diet stimulates reproduction The two factors, water content and the nitrogen content of the sap, are interdependent, but it would form an interesting problem in nutrition to find which of the two is of the greater importance in any particular case

The specific rôle of water in the metabolism of plant and insect is not mentioned by Uvarov in his recent memoir and review of the literature on insect nutrition and metabolism (*Trans Ent Soc*, *London*, Pt 2, December 1928), although considerable attention is paid to the related subjects of the food of insects and the influence of diet on growth and reproduction There is also no reference in "Filterable Viruses" (Ed by T M Rivers, Baillière, Tindall and Cox, 1929) to the water relationships in plants susceptible to virus diseases, but it is a frequent observation that plants so infected have, in general, poorly developed root systems

In order to understand these diseases more fully, much further work will be necessary on insect nutrition and metabolism, their habits, host-plants, and rates of reproduction, and in particular on the specific biological relationships which appear to exist in many cases between the insect and the disease it transmits In this connexion it seemed desirable again to direct attention to the water balance of plants as a factor in their resistance to insect pests

Starch Envelopes of Pyrenoids

THE pyrenoids are colourless masses of protein associated with the chromatophores in several classes of the Protophyta They have been most studied in the Isokontæ (Boubier, *Bull Herb Boissier*, **7**, p 451, 1899, Bourquin, *Bot Gaz*, **64**, 426, 1917), where they are embedded in the substance of the chloroplast and are covered with an envelope consisting of small starch grains which are the last to disappear under starvation conditions The pyrenoids are generally regarded as reserve protein stores During the formation of reproductive cells they disappear more or less completely

Starch formation and accumulation does not seem to be confined to the neighbourhood of the pyrenoids According to Timberlake (*Ann of Bot*, **15**, 624, 1901), however, in the case of *Hydrodictyon*, and to Carter (*ibid*, **33**, 475, 1919) in the case of *Cladophora*, all the starch is derived from the pyrenoids

If we regard the pyrenoids as storehouses of reserve protein, the exact conditions and the mechanism by which this reserve is utilised are not yet fully established Steinecke and Ziegenspeck (*Ber Deutsch Bot Ges*, **46**, 678 681, 24/1) are of the opinion that the pyrenoids function as a storehouse for a prophase of a starch building ferment, a view which has been adversely criticised by Czurda (*ibid*, **47**, 181 185, 25/4)

The observations of Timberlake and Carter indicate that a reaction as shown by the equation

Protein $\longrightarrow$ Carbohydrate + Protein Fission Product

is possible

The reaction might in fact be considered as reversible, thus, Protein $\rightleftharpoons$ Carbohydrate + Protein Fission Product

In a preliminary series of experiments on the action of ultra violet light on protein solutions, results have been obtained which may throw some light on this question of protein carbohydrate metabolism in plants A 0 50 per cent solution of recrystallised ovalbumin at any reaction increases in hydrogen ion concentration on irradiation In the case of ovalbumin, when the reaction is near that of the isoelectric point, the protein is partly or completely denatured Thus with an initial pH value of 5 92, four hours' irradiation partly denatured the protein and caused the reaction to drop to pH 5 33 The coagulum was soluble in alkali and not soluble in acid and was probably an acid metaprotein The most striking feature of the experiments was that formaldehyde was distinctly recognisable by its odour in several instances of prolonged irradiation

Irradiation in presence of chlorauric acid produced a splendid gold sol, but only if the solution was acidic in reaction The gold sol increased in depth of colour

when the solution was afterwards heated An irradiated solution of ovalbumin with a perceptible odour of formaldehyde gave on distillation an aqueous distillate neutral in reaction, and whilst not responding to the pyrogallol and nitroprusside phenylhydrazine tests for formaldehyde, it produced a brown coloration with ammoniacal silver nitrate on boiling

The conclusion is that formaldehyde (or some substance resembling formaldehyde) is produced on irradiation of ovalbumin by ultra violet light The increased acidity is probably due to conversion of amino groups to methylene derivatives by the aldehyde (Henriques and Sørensen, *Zeit physiol Chem*, 64, 120, 1909) An alkaline reaction evidently favours such a combination, with the result that no reducing action (as, for example, on gold chloride) can take place

That formaldehyde functions as a precursor of hexoses and starches is generally accepted, and hence it is conceivable that the protein of the pyrenoids can give rise to the carbohydrate of their envelopes

The action of ultra violet light on proteins is being further investigated

Globular Lightning

PROF MARCHANT's account of a case of globular lightning inside a room, in NATURE of Jan 25, leads me to think that the publication of the details of two somewhat similar instances which occurred in the dining room of the Faulhorn Hotel, near Grindelwald, are worth putting on record

I did not witness either occurrence myself, but I questioned Fraulein Suzanne Iacci, the manageress of the hotel, on the subject on Aug 2, 1925, her answers are given in inverted commas

It seems probable that both induction and stationary waves are concerned with the phenomena

"About 5 P M of a hot fine July afternoon in 1921, I was in the dining room of the hotel, with my sister Margaret and six other guests A dark cloud was noticed approaching from the east, but neither rain, hail, nor snow fell before the occurrence of the fire balls, and only distant lightning had been observed Suddenly from the air inlet of the large stove, in which a small wood fire was burning, came, practically simultaneously, a large number of very bright round balls of various colours, the largest perhaps nearly as large as my head Almost at the same moment, a dreadful deafening explosion occurred, and the balls had all vanished The room was full of a grey smoke —perhaps disturbed dust—and a strong peculiar odour was observed I opened the doors to clear the air, and then examined the room I could find no signs of scorching on the curtains, flowers, or the unenclosed stuffed birds and animals in the room The fire had not been disturbed, and none of the fuel was ejected The guests who were nearest the stove momentarily experienced a slight electric shock, but no one was injured I myself was farther away, and did not feel any shock

"In July 1914 my sister Louise and Madame Bohren, the wife of the proprietor, were in this same room during a hailstorm, and they had a similar experience On this occasion the stove was not alight No damage was done on this occasion either

"During thunderstorms I always warn people not to stand too close to the stove, as they sometimes receive nasty electric sparks There is no record of any serious injury here since the hotel was built in 1830"

I afterwards interviewed the sister (Margaret) and Mme Bohren in Grindelwald Their account nearly agreed with the above, though to the latter the incandescent spheres of 1914 appeared of the same colour and size—"reddish and of about the size of my two hands" I should add that this hotel stands in a very exposed position only a few feet from the summit of the Faulhorn (8800 feet) It is surrounded by a series of lightning conductors The closed cylindrical stove was 5 feet 4 inches high and 2 feet 2 inches diameter It stood just away from the wall of the room on a wooden plank The air inlet referred to above was rhomboidal in shape—the sides being 1 7 cm and 4 3 cm in length The iron flue at the top was 11 cm in diameter For warming purposes this flue passes horizontally through several bedrooms on the floor above the dining room before issuing through the roof some 20 feet above the stove I have a small photograph of this stove and will lend it to anyone interested in it

Since the last occurrence the stove has been 'earthed', and a lightning conductor has been fixed above the chimney

Improvements in the Peel-Method of Preparing Sections of Fossil Plants

THE peel method of preparing sections of fossil plants was briefly described by me in NATURE of Oct 13, 1928, p 571 The use of cellulose esters was recommended for preparing peel sections Since writing that letter, I have performed experiments on the use of gelatine instead of cellulose esters, and have obtained results which fully justify the adoption of gelatine on many occasions in which this type of section is required For small sections the cellulose ester solutions are more easily applicable, but for large sections, for example, those exceeding 2 sq decimetres in area, gelatine is preferable

Gelatine peel sections are non inflammable and involve in their preparation none of the unpleasant smelling and sometimes actually noxious solvents necessary when using cellulose esters There is very little difference in translucency, cellulose pell sections are perhaps a little clearer than gelatine, but this advantage amounts to little

The surface of the petrifaction is prepared and etched with acid in the manner described before, washed, and then, *before* the surface is allowed to dry, a hot solution of jelly containing a certain quantity of glycerine and formalin is poured on to the surface The quantities and proportions used must be determined by experiment To cover a surface 1 sq decimetre in area it is necessary to use about 2 grams of fairly pure gelatine such as that used in making bacteriological cultures, 50 c c water, 0 5 c c glycerine, and 0 5 c c formalin (40 per cent) The surface must be surrounded before the etching process with a rim of plasticene or some other substance and should be levelled by means of a spirit level. The water and glycerine are mixed, heated, and the jelly stirred until dissolved The heating is continued until the mixture is at a temperature of about 60° to 80° C The formalin is then stirred in quickly and the solution is immediately poured over the surface of the petrifaction The jelly is allowed to set, and then the specimen under treatment may be removed with its adhering layer of jelly to a warm, well-aired place to dry Dust must not be allowed to settle on the jelly When the jelly has become dry it may be peeled off As it is always more brittle than cellulose

there is more difficulty in starting the peeling process, but on the other hand when once a satisfactory start is made it peels off more readily

Large sections have been prepared (about 20 sq decimetres in area) with scarcely a detectable flaw and with the cellular details of the fossil plants perfectly represented Gelatine peels may be cleared in zylol and mounted in Canada balsam solutions

Matthew Island

On May 7, 1928, when on the s s *Suva*, I passed close to Matthew Island, in the South Pacific, but was unable to land It is about 200 miles from the nearest of the Loyalty Islands, and about 170 from the southernmost of the New Hebrides It is known to be inhabited by numerous sea birds, and it is possible to see green vegetation on the sides of the central mass I could not see any coconut palms From the heavy surf dashing against the shore, it appeared that landing would be difficult, but I was told that the island was used for target practice by British gunners during the War Owing to the position of the island, and the many interesting problems connected with the fauna and flora of the New Caledonia and New Hebrides groups, any endemic terrestrial animals or plants found upon it would be of extraordinary interest It may be that none will be found, but I think the chances for discovery are good enough to justify a careful search, especially in view of the richness of Norfolk Island and Lord Howe Island Perhaps there are some records, but I have not heard of any, and believe that no careful investigation has ever been made

Matthew Island was discovered in 1788 by Capt Gilbert on the *Charlotte* It is said to be 465 feet high, of volcanic formation, composed principally of basaltic rock The outline is roughly triangular, each side about a third of a mile long It may perhaps be regarded as the southernmost point of the New Hebridean chain, although the nearest relatively shallow water is that of the New Caledonian group

The Middleton Reef, north of Lord Howe Island, has a fair sized rock above the sea, but this is undoubtedly devoid of terrestrial life other than sea birds

Boulder, Colorado, Feb 12

The Moment of the Bromine Nucleus

The following interpretation has been given by Kiess and de Bruin (U S Bureau of Standards *Journal*, in print) of the strong bromine arc lines

Int	λ	Combination
15	6631 64	$5s\ {}^4P_{5/2} - 5p\ {}^2D_{5/2}$
12	6559 81	$5s\ {}^4P_{5/2} - 5p\ {}^4S_{3/2}$
20	6350 74	$5s\ {}^4P_{5/2} - 5p\ {}^2P_{3/2}$
12	6148 62	$5s\ {}^4P_{5/2} - 5p\ {}^2D_{3/2}$

These lines have thus the same end-level ${}^4P_{5/2}$ originating in the coupling of a $5s$ electron

The hyper fine structure of bromine lines has been investigated by Kimura (*Mem Coll Sci*, *Kyoto*, **4**, p 133 1920) and by Hori (*Mem Coll Sci*, *Kyoto*, **9**, p 312, 1926) The above mentioned lines are quadruplets consisting of a series of components of decreasing spacing and intensities The distances between the components are in all cases practically the same $\Delta\nu = 0\ 19,\ 0\ 13,$ and $0\ 08$

In combining the value $i = 3/2$ with the value $j = 5/2$, one finds the right number of hyperfine structure levels, namely, four Further, one should expect on the basis of the interval rule for the ratio between the hyperfine structure levels 4 3 2, which is in good agreement with the observed values 4 2 7 1 7 It seems, therefore, probable that the moment of the bromine nucleus is $i = 3/2$

The Zeeman effect of these hyperfine structures will be investigated

T L de Bruin

Laboratory 'Physica' of the University
of Amsterdam, Feb 6

Zoological Nomenclature Acarine or Insect?

In answer to Dr C W Stiles's letter in Nature of Feb 9, 1929, p 207, in which he states "that application for suspension of the rules has been made in the case of *Nycteribia* Latreille, 1796, monotype *Pediculus vespertilionis* Linn, 1758 The Commission is requested to set aside the monotype designated in 1796 and to validate *Nycteribia pedicularia* 1805 as type of *Nycteribia*", I desire to point out that as Latreille's description is based on an insect, and as the so called monotype is an acarid, it follows that the name Nycteribia cannot supplant *Spinturnix* for the genus in which *Pediculus* [Scopoli used *Acarus* —Ed Nature] *vespertilionis* Scopoli 1763 is now placed

1 *Pediculus vespertilionis* Linné 1758 is a *Nycteribia* from his diagnosis, therefore no emendation is necessary

2 *N pedicularia* Latreille 1805 is the same species

3 *N vespertilionis* cannot be an acarid as suggested by the pretext for alteration

Anthony Musgrave
(Entomologist)

The Australian Museum,
Sydney, Dec 13, 1929

The foregoing letter from Dr Musgrave, one of the world's best known authors on the *Pupipara* (in which *Nycteribia* is classified), presents one angle of the triangular problem upon which the International Commission on Zoological Nomenclature has been requested to render an opinion (1) From 1763 to 1796, *Pediculus vespertilionis* Linn, 1758, was interpreted as an acarine on basis of Frisch's (1728) figure cited by Linnæus in 1758 (2) From 1796 to 1900 it was interpreted as an insect on basis of Latreille's description From 1900 to date it has been interpreted by some authors as an acarine, by others as an insect (3) If Linné's diagnosis be compared with the description by Frisch, the probability is seen to be present that Linné's *P vespertilionis* was a composite species consisting of an acarine plus an insect

In the communication printed in Nature of Feb 9, 1929, p 207, the Commission complied with the routine prescribed by the International Zoological Congress, that is when (as in this case) it may become necessary 'to suspend the rules' and to act under its 'Plenary Power', in order to settle certain cases of controversial nature, the Commission is required to give public notice of at least one year of its possible action, to enable every side to the controversy to submit its point of view

We are forwarding Dr Musgrave's argument to Mr Frederick Chapman, the Australian member of the International Commission, and to the Secretary of the Commission —Editor

Diving *

By Prof LEONARD HILL, F R S

THE new submarine escape dresses designed by Mr R H Davis have been successfully used at a depth of 130 ft at Loch Long and have since been adopted by the Admiralty Every man in the submarine service will have to have one, just as the soldier has his gas mask In case of accidental sinking of a submarine, each man will at once put on the dress and partly fill the breathing bag from the small oxygen cylinder which is fixed below the bag, and then breathe in and out of the bag through a cartridge of soda lime which is put inside to absorb the exhaled carbon dioxide Then the submarine will be flooded so as to equalise the air and the water pressure, and allow a hatch to be opened through which the men will float up one by one and reach the surface, the breathing bag, acting as a balloon, will take them there There is an escape valve provided for preventing over distension of the bag

In using the submarine escape dress, men must be trained to fill the bag only partially with oxygen, so as to allow expansion of the gas on coming up There is no risk of bubbles of nitrogen forming in the body fluids through coming up quickly, even from a depth of 300 feet, because oxygen has been breathed from the time the air pressure was increased by flooding the submarine

In case of prolonged difficulty in effecting escape from a submarine, surplus apparatus to afford fresh soda lime cartridges and oxygen will be required If the water has entered the submarine so that the air is under pressure, the bag should be filled with expired air two thirds full and only enough oxygen added to keep it comfortably full—this to prevent oxygen poisoning In this case, just before coming out, the bag must be squeezed empty and then filled with pure oxygen and this breathed for a few minutes so as to prevent bubbling off of nitrogen in the body

The new self contained diving dress allows a diver to get an air supply from a cylinder containing a mixture of air and oxygen, an injector device being used to draw the air in the helmet through a canister of soda lime The diver is free from hose pipe and air pump, and merely carries a life line with connexion for the telephone in his helmet Arrangement is made so that he can detach this line and leave it fast outside while proceeding into a wreck, using a distance line to find his way out by

The use of this apparatus is limited to a certain depth by the percentage of oxygen which it is safe to breathe If 50 per cent oxygen is supplied in the cylinder, the diver can safely do two or three hours' work in shallow water, but he should not exceed half an hour at a depth of 100 feet For greater depths, air with smaller percentages of oxygen must be used, and experience is required to work out the most suitable method of supply If the air is kept pure by absorption of carbon dioxide by means of a soda lime cartridge, then a small oxygen cylinder will suffice to keep the percentage in the helmet at, say, 10 per cent, for deep work The reducing valve can be set to give that amount of oxygen which the diver uses per minute, but there is a risk of too little oxygen arising through extra hard work on the part of the diver, and we must bear in mind that want of oxygen does not give warning before a man loses full use of his senses An additional cylinder of air with 10 per cent of oxygen in it will have to be carried for altering the buoyancy of the dress as needed Probably the ordinary method of ventilating the helmet by a hose pipe will be used for deep work a tank containing compressed air with 10 per cent oxygen being used as the supply A ready method of partially deoxygenating air will have to be installed on the diving ship

The new submersible decompression chamber, also designed by Mr R H Davis, was used with great success at trials conducted by the Admiralty at Loch Long last summer An attendant goes down in this cylindrical chamber, which is fitted with a door top and bottom, and waits to receive the diver at a depth of 66 feet The lower door is open and water kept out of the chamber by compressed air pumped into it The chamber is lit with an electric lamp The shot rope of the diver passes through rings attached to the outside of the chamber After doing his job on the bottom he ascends rapidly to the chamber, and climbing up by a small ladder thrusts his helmet up in the chamber, so far that the attendant can cast off hose pipe and life line and take off the helmet The diver then comes right in and the lower door is shut A telephone message is then sent and the chamber is raised to deck level and decompression carried out there From the time the diver leaves the bottom, all these operations take only seven or eight minutes to carry out, the diving ship can, if need be, then proceed to harbour This is a great improvement on the old method of the diver hanging on the shot rope in the cold and dark while decompression in stages is carried out Moreover, when in the chamber the diver can breathe oxygen by means of a small apparatus, and by this means shorten the decompression time by at least one half

There are three dangers from which the diver has to be protected First, he may be poisoned by too much carbon dioxide through insufficient ventilation If one air pump suffices to ventilate the helmet at one atmosphere, an extra pump is required for each atmosphere in addition, as pointed out by Dr J S Haldane, so at 300 feet ten pumps are required Many divers have been made less efficient while at work and damaged in health by insufficient ventilation In place of so many pumps, a canister of soda lime can be arranged to purify the air in the helmet, and this is an improve-

* From the Friday evening address delivered at the Royal Institution on Feb 7

ment which will, I think, be adopted for deep diving Secondly, at considerable depths the diver is exposed to high tensions of oxygen, for example, at 300 feet, to 10 atmospheres of air, which is equivalent to 2 atmospheres of oxygen, and oxygen at any tension a little greater than 70 per cent of an atmosphere acts as a poison when breathed for more than a certain time, the time becoming shorter as the tension is raised While exposure for some days to a tension of oxygen greater than 70 per cent of an atmosphere produces pneumonia, experience has shown that the breathing of pure oxygen at a pressure of one atmosphere for a few hours, as in the use of mine rescue apparatus, has no ill-effect

Experiments have shown that animals can safely breathe 2 atmospheres of oxygen for 2 hours, but during this period both the use of oxygen by the body and the output of carbonic acid diminish, the body temperature drops and the animals become drowsy If the exposure is more prolonged, or in shorter times if the oxygen tension is higher, the animals fall into a comatose condition and finally have convulsions and die Some very important experiments were made by Bornstein at the Elbe tunnel works He breathed oxygen at 3 atmospheres (+30 lb) for 48 minutes, and two of the engineers (at the Elbe tunnels) for 30 minutes without harm He considered periods such as these set the limits to safety

In diving experiments in the United States of America in connexion with the practice of an American submarine escape apparatus, oxygen has been used without detriment for short periods up to a pressure of about twelve atmospheres, equivalent to 357 feet of water

Argyll Campbell has shown that normally when breathing air the tension of oxygen in the tissues equals 37 mm of mercury The blood in the veins coming from the tissues is normally about 75 per cent saturated with oxygen and carries 2½ to 3 volumes per cent more carbon dioxide than the arterial blood, which is 95 per cent saturated with oxygen Under high oxygen tensions in the inspired air, the tissue oxygen tensions rise, for example, from 84 mm to 430 mm of mercury, and the venous blood, being almost fully saturated with oxygen, can carry very little more carbon dioxide than arterial blood Moreover, when the tissues are in danger of oxygen poisoning, the circulation may be reduced Thus carbon dioxide is held back in the tissues and the tension may rise to poisonous heights, as was found to be the case by Argyll Campbell

It is clear, then, that for deep diving the ventilation of the helmet must be kept adequate enough to prevent even a small rise of carbon dioxide in the air breathed It must be kept in mind that, at 10 atmospheres, 0 1 per cent of carbon dioxide in the air breathed produces a tension of carbon dioxide of 1 per cent of an atmosphere, and 1 per cent produces a tension of 10 per cent The poisonous effect depends on the tension, and 10 per cent is enough to anæsthetise a man If there is difficulty in carbon dioxide being carried from the tissues owing to high oxygen tension, this difficulty must not be accentuated in the least degree by ill-ventilation of the helmet, otherwise the diver may become drowsy, and even comatose

To avoid any poisonous effect of oxygen for deep dives the percentage in the air supplied to the helmet can be halved Mr R H Davis has contrived apparatus for effecting this, that is, for supplying less oxygen during compression, and more during decompression, for diving to greater depths, air with still less oxygen in it will have to be used As pure oxygen is going to be used in the submersible decompression chamber, it is obviously best to prevent any excess of oxygen while at work on the bottom At 10 atmospheres, 2 per cent of oxygen in the air would give a diver the natural amount of oxygen Suppose, for safety sake, that 10 per cent of oxygen is used at 10 atmospheres, the nitrogen will be increased by one atmosphere, and this will have to be allowed for in reckoning the decompression period

The effect of breathing oxygen in washing out nitrogen can be shown If diuresis is established by drinking two or three pints of water, the secretion of the kidneys can be used as a measure of the nitrogen dissolved in the blood The bladder can be emptied every few minutes and samples of the urine collected with precaution to exclude contact with air The dissolved gas can be extracted by a vacuum pump, and the amount of nitrogen estimated At ordinary atmospheric pressure, there is approximately 1 per cent of dissolved nitrogen gas, at 2 atmospheres 2 per cent, at 3 atmospheres 3 per cent, and so on The effect of breathing oxygen for nine minutes during exposure of the body to a pressure of 3 atmospheres (+ 30 lb) was to lower the percentage of nitrogen in the urine then secreted to 2 1, and in the next six minutes to 0 9 Urine secreted during decompression after being at + 30 lb pressure, this time with no breathing of oxygen, contained 2 86 per cent of dissolved nitrogen, more than three times as much It is clear, then, that the breathing of oxygen quickly washes out nitrogen dissolved in the blood and tissues of the kidneys

The washing out of nitrogen from the body by breathing oxygen has been shown in another way, by Argyll Campbell and myself After taking three or four deep inspirations from a bag full of oxygen and expiring into the air so as to wash most of the nitrogen out of the lungs, a deep expiration is made and a sample of alveolar air collected, the subject then breathing through a soda-lime cartridge in and out of a spirometer containing a few litres of pure oxygen A sample is drawn from the spirometer for analysis at 3 min and 6 min, in each case at the end of a deep expiration, and the volume of gas in the spirometer being on each occasion measured At the end of the deep expiration a sample of alveolar air is also collected from the tube leading to the spirometer The volume of the residual air in the lungs can be calculated, and so, too, the use of oxygen in metabolism by the subject during the period

It is estimated that there are about 960 c c of

nitrogen dissolved in the body of a man under ordinary atmospheric pressure, say 30 c c in the blood, 510 c c in the fat, which dissolves about five times as much water, and 420 c c in the other tissues Our experiments show that about 30 c c of nitrogen per minute are washed out in the first few minutes from a man at rest, and about 50 c c from one doing stepping exercise It seems clear, then, that by breathing oxygen, and exercise, the washing out of half of the nitrogen, probably that amount which causes bubbling and severe symptoms on decompression, takes place in about 10 minutes It is safe for a diver to breathe oxygen during the time required for decompression in the submersible chamber from 3 atmospheres absolute pressure (66 feet approx depth) if the oxygen breathing allows the times of the Admiralty table set for the safe decompression of divers to be halved

Further research on animals is now being carried out to settle the point whether the formation of bubbles can be prevented by plus two atmospheres of pressure (66 ft depth) when a diver is quickly decompressed from 300 ft to that pressure after a prolonged stay on the bottom Possibly a stage will have to be given at 99 ft If the diver is supplied with, say, 5 per cent of oxygen at the great depths, he can safely begin to increase the oxygen in his helmet as he climbs up from the bottom, using a small cylinder of pure oxygen for this purpose, and then arriving at the submersible decompression chamber be ready to breathe pure oxygen at plus two atmospheres and during the decompression from that pressure When a bottle of champagne is opened in a chamber at plus two atmospheres, it appears flat, as this pressure stops the formation of bubbles and the gas escapes quietly In the trials at Loch Long, divers came up quickly from 300 ft to 66 ft and suffered no harm It is important that the deep sea divers go down fasting with the least gas in his alimentary canal Gas formed therein mechanically obstructs the circulation by expanding during decompression and enhances the danger of bubbles forming in the blood Out of twenty-four well-fed guinea pigs compressed for 1 hour to plus 100 lb and decompressed in five minutes, nineteen died, out of twenty-four fasting guinea pigs only eleven died None died when oxygen was given during the period of decompression

The U S Navy is experimenting with helium and oxygen, helium has less solubility and greater diffusivity than nitrogen, and good results are reported We have no available helium

There are certain other dangers to which the diver is exposed, as were evidenced by the salving of the *S 51* submarine by the U S Navy The inlet valve may become blocked by ice due to freezing of water condensed out of the air pumped down the hose pipe in wintry weather when the salt water at the bottom of the sea is below freezing point One diver was drawn up just in time, half suffocated, another was far inside the submarine when this happened, but managed to knock his valve free of ice by striking the outside with a spanner The air-supply after that had to be freed from water vapour for such wintry diving It is astonishing that the divers can work with their hands exposed to such cold water even when gloved A thick, knitted wool glove containing air in its meshes with a rubber glove outside is, of course, the best protection against cold

Another danger is the outlet valve becoming jammed through sand getting into it when lying down and tunnelling as those American divers did through clay, using a fire hose and high pressure water to cut out the clay If the outlet valve closes, a diver may have his dress blown out and be spread eagled before he can shut off his air supply or open his spit cock and use that as an air outlet If his telephonic message to cut off the air be not heard his dress will be burst This actually happened to Eddy, a famous diver, but another diver witnessed the accident and, telephoning the news, Eddy was drawn up in time, put in the recompression chamber, and saved To be blown up is dangerous, first, because of the rapid decompression, and secondly because of the risk of the helmet hitting the bottom of the attendant ship If a diver be blown up to the surface, he must be at once sent down again after letting out excess of air, or have his helmet taken off and be rushed into the recompression chamber

The courage and presence of mind of divers is shown by the story of a diver named Smith who, when tunnelling out the clay and getting near the keel of the submarine *S 51*, had the clay walls of the tunnel fall in upon him He telephoned for help, but managed to turn round the nozzle between his legs and force out the clay and so escape, then, telephoning he was all right, he went back again into the tunnel and completed the job, and this down in the dark at a depth of 130 feet

The oxyhydrogen flame has been adapted for use under water, and large thicknesses of metal were quickly burnt through by this means in the salving of *S 51*, by Commander Ellsburgh

The 'iron man' designed in Germany and used in wrecks by Italian divers is an observation chamber with jointed limbs which allow a certain amount of awkward movement The joints have ball bearings The diver, shut inside, is at ordinary atmospheric pressure and breathes oxygen, having the exhaled carbon dioxide absorbed by soda lime He can use the oxygen supply also to alter the buoyancy of the iron man There are glass discs for observation, and in dark water a powerful electric lamp has to be lowered down for him to see by At a depth of 100 feet the sunlight appears as moonlight, and at 200 feet as starlight Tools are affixed to the end of the 'iron man's' arm, and the diver works these by scissor like handles inside The diver in the 'iron man' cannot use his sense of touch, and prolonged training and good lighting are necessary for effecting any skilled work After a dozen trials in it, one diver failed to shackle a rope on to a buoy The diver in the 'iron man' can guide a charge of guncotton, or a grab for seizing hold of wreckage, but is not capable of very skilled work

Mineralogy at Cambridge

THE report of a syndicate appointed by the Council of the Senate of the University of Cambridge to consider the position of mineralogy in the studies of the University was the subject of a lengthy discussion in the Senate House on Jan 28 The recommendations contained in this report were summarised in a leading article in NATURE of July 13, 1929 They have since been reported on by the University Boards concerned and by the Committee of the Natural Sciences Tripos

The proposals for the creation of two departments —one of mineralogy and petrology, and one of crystallography—met with approval in principle, but the Financial Board had already indicated that no money was forthcoming to meet the additional expenditure involved except "at the expense of existing University activities" No definite opinion is expressed on the proposal to make 'half subjects' in the examination of crystallography and of mineralogy and petrology, as this involves problems of some difficulty It is, however, suggested that the regulations for the Natural Sciences Tripos should receive general reconsideration

The Syndicate included distinguished representatives of every science bordering on mineralogy, and it was perhaps natural that its report (which was unanimous) should have dealt mainly with the relations of mineralogy to other sciences The discussion, however, was left entirely to mineralogists and geologists, among whom the report has aroused very considerable interest and some controversy That this interest is not confined to resident members of the University is indicated by the fact that speakers in the discussion included two professors of geology in London, the professor of geology in Edinburgh, and four of the curators of the two great collections of minerals and rocks in London (the Natural History Museum and the Museum of Practical Geology) The resident members of the University participating in the discussion (which occupies twelve pages in the *Cambridge University Reporter*, Feb 11) were the professors of geology and mineralogy, the chairman and secretary of the Syndicate, the reader and the lecturer in petrology, the lecturer in structural crystallography, and two other members of the staff of the Department of Mineralogy

The speeches of the professor of mineralogy and of the lecturers in petrology and in structural crystallography outlined the possible scope and the present difficulties affecting teaching and research in their subjects

The lecturer in structural crystallography spoke whole heartedly in favour of a separate Department of Crystallography, and with this recommendation of the Syndicate the other speakers (with two exceptions) seemed disposed to agree The professor of mineralogy regretted that the Syndicate had not considered the possibility of housing crystallography, mineralogy, and petrology under one roof, and quoted the examples of Zurich and Göttingen Mr Hallimond felt that any Department of Mineralogy had a reason for having an X-ray department on the crystallographic side, while many parts of the X ray researches, involving some of the most advanced theories of modern physics, really belonged to that Department Additional point was given to this suggestion by the remarks of the lecturer in structural crystallography, who seemed to envisage a department for the X ray study of the solid state, and foretold a remodelled teaching of crystallography which evidently gave some of the mineralogists seriously to doubt whether "the teaching of such crystallography and crystal physics as is required by students of mineralogy and petrology" would be provided by the new department Another speaker made it clear, however, that the need in X ray research of a sound knowledge of geometrical 'surface' crystallography was fully realised

On the recommendation to bring mineralogy and petrology into one department and to house them in a new building adjacent to the Sedgwick Museum, the speakers were almost all in agreement, The only important difference of opinion revealed is on the extent to which the study of advanced petrology should be restricted to students of geology, and whether the association of the newly constituted department should be quite so close as that provided for in the recommendations for the reorganisation of the Tripos

Non residents with experience in other universities spoke highly of the teaching of both mineralogy and petrology in Cambridge, and emphasised the need for maintaining its schools in these subjects in the pre eminent positions which they have occupied in the past On the other hand, it is evident that many speakers considered that the progress of both studies was seriously hampered, if not actually stopped, for want of adequate accommodation and facilities for research along modern lines Particular stress was laid on the urgent need for a laboratory for research in experimental petrology on the lines so successfully followed at the Geophysical Laboratory of the Carnegie Institution of Washington

The lecturer in petrology made a good point when he remarked that research and Part II work in mineralogy was spasmodic, and therefore unsatisfactory, because of the few openings available for men trained in mineralogy alone The union with petrology (and geology) would, he thought, induce a steady flow of students to take up Part II work and research in the two subjects Prof Watts spoke strongly in the same sense of the extensive increase in the possibility of research which would be offered by the united departments He also reminded his hearers that a proposal to establish a laboratory in Cambridge on the lines of that of the Carnegie Institution of Washington had been before the Conjoint Board of Scientific Societies several years ago and had been abandoned only because of expense

Following publication of the report of this discussion, notice was given of a Grace approving in principle the policy of dividing mineralogy and petrology for the purposes of teaching and research into crystallography on one hand and mineralogy and petrology on the other The Grace was passed unopposed on Mar 8 This is the first part of the Syndicate's report which received almost unanimous support in the discussion the second was the desirability of housing mineralogy and petrology in a new building, thus making room for crystallography in the old It is to be hoped that the means will speedily be found to build and equip the new laboratories and thus to make possible in Cambridge the kind of teaching and research on the need for which there seems such unanimity of opinion among competent judges It may be remarked that every branch of research mentioned in the discussion, both in X ray work on crystal structure, and in the study of ores, of rocks, and of silicate melts, has its direct application in industry

Obituary.

PROF F M EXNER

FELIX M EXNER, professor of geophysics in the University of Vienna, director of the Zentral anstalt fur Meteorologie und Geodynamik, Vienna, and joint editor with Suring of the *Meteorologische Zeitschrift*, died in Vienna on Feb 7 Exner, who was a son of the physiologist Sigmund Exner, was born in Vienna on Aug 23, 1876 He was educated at the University of Vienna, where he graduated as Ph D in 1900 After ten years as assistant at the Zentralanstalt, he became professor of cosmical physics at the University of Innsbruck in 1910, returning to Vienna in 1917 to take up the post of director of the Zentralanstalt and professor of geophysics

Exner was a very active research worker in meteorology and allied sciences, and published a large number of papers in the proceedings of the Vienna Academy of Sciences, the *Meteorologische Zeitschrift*, the *Annalen der Hydrographie*, and various other journals These papers cover a wide field He was particularly interested in the mechanism of changes of pressure, and in the earlier years, in the correlation between meteorological factors over different regions of the globe He treated the latter question at great length in a paper in the proceedings of the Vienna Academy of Sciences, vol 122, the work having been largely carried out during a visit to the United States

Exner was an industrious and sound, rather than a brilliant worker, and he will be remembered for his treatise " Dynamische Meteorologie ", rather than for his original work This book, which gives a very clear exposition of the outlook of the Austrian school of meteorologists, stands alone to day as the only available exposition of the mathematical aspects of meteorology Its preparation, which must have involved years of unremitting labour, was doubtless facilitated by his appointment to the professorship of cosmical physics at Innsbruck The Austrians are fortunate in having this professorship, to which they can appoint a young man to enable him to carry on research work or authorship unimpeded by official duties, and this professorship has usually been the avenue of approach to the post of director of their meteorological service

There is no text book in the English language which is strictly comparable with Exner's The dynamical methods followed by Exner, Margules, and others of the Austrian school of meteorologists have not been very widely used in England or the United States, and as a result, English text books are either descriptive or physical, rather than mathematical Thus Exner's book has met a widely felt need among meteorologists, and is one of the few books of which we can say with complete honesty that it is indispensable to any serious student

Exner was also the author of an article on dynamical meteorology in the " Enzyklopadie der mathematischen Wissenschaften", but a more out standing service to science was the publication in 1922 of a revision of Pernter's classic text book on meteorological optics He also prepared the European portion of " World's Weather Records ", published by the Smithsonian Institution

As director of the Austrian meteorological service, Exner was a member of the International Meteorological Conference His pleasing personality won him the respect and liking of his international colleagues, and his death will be regretted by meteorologists throughout the world D B

DR G G CHISHOLM

GEORGE GOUDIE CHISHOLM, who was the first lecturer (1908) and later the first reader (1921) in geography at the University of Edinburgh, and acted also as secretary of the Royal Scottish Geographical Society from 1910 to 1925, died very suddenly in Edinburgh on Feb 9 Born on May 1, 1850, he was thus on the eve of completing his eightieth year, though few of his associates realised the fact, his mental vigour being unimpaired to the end, while even physically there were few signs of age

A native of Edinburgh, Dr Chisholm attended the Royal High School there and took the degrees of M A and B Sc at the University, which after his retirement in 1923 bestowed upon him the LL D He spent his earlier life in Scotland, going to London in 1895 There, until the date of his Edinburgh appointment, he was engaged in lecturing and literary work, and soon became a prominent figure at the annual meetings of the British Association, being president of Section E (Geography) in 1907 Of his writings, those through which his influence was most felt were his " Handbook of Commercial Geography ", first published in 1889, of which an eleventh edition appeared in 1928,

and "Longmans' Gazetteer of the World", of which he was editor, which first appeared in 1895 and has been often reissued Both works show that rigorous accuracy in detail, based upon pro found and wide research into original sources, and that sober and balanced judgment which were his outstanding characteristics

Dr Chisholm may, indeed, be said to have been one of the founders of scientific geography, particularly from the economic side, within Great Britain Not only did he show that it demanded as exact scholarship, as wide knowledge as the subjects which had been recognised earlier as worthy of academic rank, but also at a time when, with the apparently sudden recognition of its interest and wide ramifications there was grave risk of hasty generalisation, he insisted upon the need for precise and, if possible, statistical proof of fundamentals Rigidly conscientious himself, and with a passion for accuracy and completeness of statement, he was peculiarly impatient of slovenliness, whether in speech or thought, and if modern geography in Great Britain may seem to have developed relatively slowly, it is to Dr Chisholm largely that we owe the fact that its foundations have been well and truly laid

Dr Chisholm's influence also extended far beyond the limits of his own country His "Handbook of Commercial Geography" had the rare distinction of being translated into Arabic, and he carried on an extensive correspondence with geographers, economists, and others throughout large parts of the world It was characteristic that his handwriting was clear and precise to the end and that he would give to letters, even on trifling matters, the same care and attention as to his own special work His help and advice were, in consequence, constantly asked for, and so freely given as to bring him into contact with a wide circle Though never in much sympathy with the narrowly nationalist Scottish point of view, he was a Scot of the best type, upright, honourable to the last degree, fair minded, indifferent to worldly advancement, but profoundly concerned with the deeper problems of man's destiny, and too clear-sighted to be content with easy solutions Even apart from his influence on economic geography and history, which was both wide and deep, the example he set of a life devoted to the search after knowledge was an inspiration to all who knew him

---

We regret to announce the following deaths

The Hon Edward Gerald Strutt, C H, past president of the Surveyors' Institution and agricultural adviser to the Board of Agriculture during the War, on Mar 8, aged seventy five years

Prof Eugenio Rignano, professor of theoretical philosophy at the University of Milan and editor of *Scientia*, on Feb 9

News and Views

Sincere regret will be felt throughout the world of science at the destruction by fire of a large part of Lord Rayleigh's laboratory at Terling Place, Chelmsford, Essex, on Mar 7 After taking his degree at Cambridge in 1865, the late Lord Rayleigh found great difficulties in getting opportunities for experimental research or instruction in laboratory work Three years later he started experiments on his own account at Terling Place, and from there produced a number of papers which at once secured for him a position as a leader in physical science When he resigned from the chair of experimental physics at Cambridge in 1884, he continued his researches in his private laboratory, and it was there that he carried out the precise determinations of the density of nitrogen which led to the discovery of argon The simplicity of the apparatus used by the late Lord Rayleigh is well known, and most visitors to the laboratory were astonished that results of prime significance could be obtained with such modest equipments We are glad to know that most of this historic apparatus has been saved as well as all books and papers belonging to the late Lord Rayleigh

The upper storey of the laboratory at Terling Place—originally a stall loft—has been burnt out, it was here that the main work on argon was done Among the pieces of historic apparatus which have been destroyed are the original Rayleigh refractometer and the manometer used for adjusting the pressures of gases to an accurate standard in the weighings of nitrogen, hydrogen, and oxygen Most of the present Lord Rayleigh's chief working instruments have also been destroyed and much preparatory work for experiments in progress is gone The apparatus thus lost includes several valuable spectrographs, quartz apparatus and lenses for investigating the optical properties of mercury vapour, air pumps, equipment for measuring the light of the night sky by photo electric cells, and other instruments used in recent or current researches It is distressing to have to record a disaster of this kind, and we ask Lord Rayleigh to accept the sincere sympathy of scientific workers everywhere at the losses he has suffered and the consequent interference with his research work

The Department of Scientific and Industrial Research has, since the inception of research associations, always emphasised that the associations, to be eligible for grant from the Department, must secure adequate financial contributions from industry itself While the securing of this support from the great industries has not been an easy matter, it is gratifying to find that in several of the most important industries of Great Britain a general levy is made in order to provide funds for particular research associations The report of the council of the British Research Association for the Woollen and Worsted Industries for 1929–1930 indicates that this Association is about to complete an arrangement under which the wool textile industry will submit to a voluntary levy on imported wool, mohair, and so on, as well as to a levy on those processing sections of the industry which do not pay the levy on the raw material The income which will

thus become available, together with the generous assistance which is being given by the Empire Marketing Board, the Ministry of Agriculture, and by the Dominions of South Africa, Australia, and New Zealand, should ensure that the future work of this important Research Association shall be conducted on a scale which the importance of the industry to the Empire as a whole properly demands

The British Research Association for the Woollen and Worsted Industries has continued to devote its attention to fundamental problems of research into the properties of individual hairs and fibres, as well as to technical and more practical problems of the trade itself The determination of Young's modulus for the wool fibre appears to indicate that plastic flow occurs in the fibre after the initial rapid change of length due to change of load If the measurements are made quickly, the extension of fibre appears to be proportional to the load over small ranges of change of load, and it exhibits negligible hysteresis The examination of the cultivation of skin and hair by tissue culture methods, and of the effect of diet on the characteristics of the fleeces, is being continued The result of the examination of samples of wool for mean fineness has indicated the extraordinary variability which occurs over very small areas This condition constitutes, of course, an important problem for the wool sorter, and, as such, is of sufficient practical importance to justify the most exhaustive experimental examination An important practical application from the chemical work of the Association may arise as the result of an investigation which appears to indicate that low quality and waste woollen materials may be dissolved and spun in the manner which has now become familiar in the production of artificial silk yarns Yarn has already been produced from a mixture of wool and cellulose, and solvents have been found which may make possible the production of a similar all wool yarn

From time to time references have been made in Nature and elsewhere to the need for authoritative portrayal and dissemination of the scientific point of view It is, of course, neither useful nor possible that everyone should be trained to elucidate scientific facts or substantially to understand the implications of properties and behaviour, nor even is it reasonable that he should with much labour and exclusion of other important affairs acquire that foundation of special knowledge which would enable him to do so On the other hand, it is clearly desirable to show the general public that science does not depend for its advance on the intuition and 'formulæ' of a few 'brilliant inventors' so much as on ordered, if sometimes laborious, experiment and deduction It needs to be constantly advertised that chemistry, for example, progresses because chemists make use of strategy and tactics which they have been able to develop by applying scientific methods of thought and by consistently employing the results of scientific inquiry

If the problems of chemistry can be solved thus, so also, by similar appropriate methods, can those of other factors in the life of the individual or his community In a recent issue of *The Listener*, Prof Arthur Smithells made a noteworthy contribution to the education of the general public in this particular Confining himself to simple, fundamental facts and to the study of their relationships, he succeeded in exposing in a pleasant, conversational manner something of the working of the experimenter's mind and something of the way in which our knowledge concerning combustion was acquired The B B C is wise to include in its publication devoted to raising the general standard of culture such an article as that contributed by Prof Smithells Whether the B B C can assist would be students of chemistry in their actual studies is, of course, entirely another matter When telephony and television are joined by radio olfaction, who knows what it may not be possible to broadcast?

At the annual general meeting of the Institute of Chemistry, Prof Arthur Smithells, the president, in moving the adoption of the report of council, made some observations on the question of chemical training, urging in particular that the burden now put upon the student is excessive and too apt to result in undigested knowledge of what are regarded as the higher things of chemistry, with accompanying neglect of what is more simple and basic He thinks that the courses have become congested and the pace too rapid, though he acknowledges the great improvement that has taken place in schools of chemistry in Great Britain It is now no longer necessary to go abroad for the latest or the best in any division of the science we are, in a way, doing too much rather than too little He alluded at some length to the ways of teaching and work which prevailed in Bunsen's laboratory at Heidelberg as illustrating the kind of conditions under which, he believed, the early training of the chemist might be more satisfactorily conducted Prof Smithells said he had only touched on one part of a very large question and was concerned to arouse interest in it rather than to lay down any law, the education of the professional chemist is really an important question of the day and calls for the most careful consideration The report of council shows that the roll of the Institute has increased by 156 members and 20 students, that the Institute is in a sound position financially, and that the committees of the council and local sections have been actively engaged in the interests of the profession of chemistry The Meldola Medal was awarded to Dr R A Morton, of Liverpool, and the Sir Edward Frankland Medal and Prize to Mr B W Bradford The officers and members of Council for the ensuing year were elected, Dr G C Clayton being elected president in succession to Prof Smithells, who has occupied the chair during the past three years

As a result of heavy and long continued rains at the end of February and the beginning of March, disastrous floods have occurred in southern France, entailing enormous damage to property and the loss of several hundred lives The floods reached their greatest intensity in the valley of the Garonne and

its tributaries, especially the Tarn, which originate in the southern Auvergne Mountains Few details are yet available, but it appears from the *Bulletin Quotidien d'Études*, published by the French Meteorological Service, that the heavy rain was associated with a persistent strong south easterly wind blowing from the Mediterranean Even on the low ground of the coast and of the Rhone valley, falls of two or three inches in a day were reported from several stations on Feb 28 and Mar 1, and where the moist wind struck the higher ground one would expect the rain to be very much heavier The rivers flowing westward from the Auvergne Mountains occupy deep narrow valleys which offer no opportunity for the floods to dissipate, and the water appears to have risen with such rapidity that the inhabitants of the valley towns were caught almost unawares Where the swollen streams debouched on the low ground of the main Garonne valley conditions were even worse, and the greatest disaster of the week occurred at Moissac, near the junction of the Tarn and Garonne The report says that the Tarn burst its banks, and the town was almost entirely destroyed

IN his Huxley lecture to the University of Birmingham, delivered on Mar 6, Sir William B Hardy dealt with "The Physical Basis of Life", which was the subject of one of Huxley's essays in 1868 He asked if we could still be as sure of the soundness of Dujardin's postulate of the one common physical basis of life, protoplasm, as Huxley was? And are we right in ascribing to this protoplasm the contradictory attributes of extreme stability and extreme instability? The view to day is that protoplasm *is* the physical basis of life, but there are as many distinct varieties as there are species of living organisms, the differences in the chemistry of their proteins giving rise to such varied forms as a whale or a gnat, a mushroom or a man All forms of organisms from the whale to the smallest bacillus are built up on this fundamental basis, but the gap between the smallest bacillus and the properties of the half dozen kinds of atoms of which it is made is immense This gap has perhaps been partly bridged by the discovery of the viruses The virus is only known by its effects, it is exceedingly potent in producing disease and yet is so small that it passes through the pores of unglazed porcelain, its dimensions may be compared with those of a sphere of 0 000025 mm diameter It possesses great power of multiplication A small drop of fluid from a dog with distemper may be diluted ten million times, and yet when a drop of this is injected into another dog, the virus may multiply to such an extent that in three days it has invaded every tissue, and if the rest of the dog could be removed, leaving the virus, the latter would form a good model of the dog These viruses possess individuality and are not interchangeable Are they to be regarded as protoplasm? We can scarcely regard so small an aggregation of molecules, 400 or 500 say, as the basis of life Perhaps they are 'first attempts' at protoplasm, parasitic on more advanced forms

IN his Friday evening discourse, delivered at the Royal Institution on Mar 7, Dr C Tate Regan spoke on "Angler Fishes" In off shoots of the perch tribe the spinous dorsal fin is variously modified, in the angler fishes its spines have become slender and flexible, and the first is placed on the head, and serves as a line and bait Anglers that lie on the bottom have a coloration that harmonises with their surroundings and tends to conceal them, their bait or lure is a flap or a tassel at the end of the line, and is used to entice other fishes near enough to be caught The anglers that float about in the middle depths of the ocean, where there is little or no light, are uniform in colour, generally blackish, and possess a luminous lure Oceanic anglers generally have a large mouth, strong sharp teeth, and a very distensible stomach, such fishes are able to swallow others many times their own size An interesting group of these oceanic anglers includes little fishes that have lost the line and lure, live at lesser depths and seek small prey by smell and sight, they have a small mouth and feeble teeth, but large nostrils and olfactory organs, one has the eyes directed forwards, and the snout is shortened in relation to stereoscopic vision All the free swimming oceanic anglers are females, and the only males known are dwarfs parasitic on the females, to which they are completely united The males, as soon as they are hatched, when they are relatively numerous, seek the females, if they find one they hold on by the mouth, then the lips and tongue unite with the skin of the female, and the husband becomes an insignificant appendage of his wife, degenerate in structure, and nourished by the continuity of his blood system with hers The evolution of the dwarfed and parasite males is difficult to explain unless it be assumed that the actions and reactions of the fishes themselves produce modifications that become hereditary

ON Mar 6 a public lecture on 'Twenty five Years Study of the Polar Aurora" was delivered at Oxford by Prof C Størmer of Oslo A large series of photographs, taken during the last twenty years, was exhibited Base lines starting from Oslo and going in several directions were employed for taking these photographs, and by means of the parallax thus shown, the height of the lower border of each aurora had been calculated This was found to be usually in the neighbourhood of 100 km above the surface of the earth, though in some instances a height of 600 800 km. was reached The height was greater in the morning and evening than at night Many of the phenomena could be explained, said Prof Størmer, by attacking the problem in a simplified form, such factors as gravitation, repulsion, etc., being omitted He attributed the aurora to a stream of negative electric corpuscles passing from the sun through the magnetic field surrounding the earth's magnetic axis This view was illustrated by a number of photographs of ingenious models In moving a vote of thanks to Prof. Størmer, Prof Lindemann observed that he hoped that the omitted factors would eventually be taken into account He thought that Prof Størmer's explanation of the 'echo' phenomenon was perhaps the most interesting feature of the whole research

SWITZERLAND is to have a 'regional' broadcasting system, somewhat similar to that which is being instituted by the British Broadcasting Corporation, with three high power stations—in the German, French, and Italian speaking sections of the country respectively—and smaller relay stations where required in the principal towns The most powerful of the new stations, a Marconi Type 'P B' 60 kilowatt broadcasting transmitter, is to be erected at Munster, about twelve miles to the north west of Lucerne, and will constitute the main 'regional' station for German speaking Switzerland It will be allotted the wave length of 459 metres To provide for 'crystal listeners' in the towns, Marconi broadcasting stations of ½ kilowatt aerial power are to be erected at Berne and Basle The new station at Berne will replace the present Marconi 1 kw 'Q' broadcasting station, which was erected in 1925 and will later be modernised and re erected elsewhere to play a part in the 'regional' plan At Basle the new station will be this town's first full time broadcasting station, the broadcasting service having previously been carried out by the Marconi transmitter at the Basle aerodrome, which is primarily employed for wireless telephony with air craft The reorganisation of the Swiss broadcasting service on the 'regional' basis is expected to be completed in 1931

IN connexion with the Physical and Chemical Survey of the National Coal Resources, which is one of the important aspects of the Fuel Research work of the Department of Scientific and Industrial Research, the Department has recently appointed a committee to deal with the West Yorkshire Coal Area Among the members are Prof J W Cobb, Leeds, Prof J A S Ritson, Leeds, Mr C E N Bromehead, Geological Survey of Great Britain, Dr C H Lander, Director of Fuel Research, and Dr F S Sinnatt, Superintendent of the Coal Survey The object of the Survey is to investigate the characteristics of the various coal seams in Great Britain with the view of their utilisation to the best advantage Local laboratories are established in each area for the examination of samples, and, when necessary, large scale investigations are carried out at the Fuel Research Station (East Greenwich) or elsewhere The Survey is now in active operation in most of the coalfields of Great Britain

THE recent award of the Roozeboom gold medal to Prof J J van Laar was made at a special meeting of the Royal Academy of Sciences at Amsterdam by Prof Schreinemakers This is the third time since Roozeboom's early death in 1907 that such an award has been made, the other recipients being Profs Schreinemakers and Tamman From the *Chemiker Zeitung* we learn the following particulars of van Laar's career, as outlined by Prof Schreinemakers Born in 1860 at The Hague, van Laar first adopted the career of a naval officer, and in that capacity he travelled over the whole world In 1881 he began to study at the University of Amsterdam, where he came directly under the inspiring influence of van 't Hoff and van der Waals In 1898 he was appointed lecturer in mathematical physics and chemistry, and in 1907 he was appointed successor to Prof Bakhuis Roozeboom, but he resigned his chair five years later for reasons of health From 1892 onwards there appeared under his name a constant stream of scientific papers, amounting to more than two hundred and covering almost every branch of physical chemistry

PROF VAN LAAR devoted much attention to the melting point and freezing point curves and vapour pressures of binary mixtures, to van der Waals' equation of state, to the formulæ and theories used in electrochemistry, and to the calculation of potentials of liquids, which are now used in physiological investigations He was also the author of several books on thermochemistry, electrochemistry, the equation of state, and a well known volume entitled "Six Lectures on Thermodynamic Potentials" His work has perhaps not received everywhere the attention which it merits This may be due to some extent to the extreme intricacy of the problems with which he has dealt But although his mathematical investigations of binary and ternary mixtures may not be easy to follow, the results are often relatively simple Van Laar indeed rendered a great service by his masterly application of strict thermodynamical principles and the equation of state to the problem of co ordinating mathematical theory with experimental results As might be expected, his work provoked a good deal of criticism, and he frequently came into conflict with those who attempted to adapt to concentrated mixtures laws which are only applicable to dilute solutions His investigations upon the borderline between the solid and liquid states under very high pressures will undoubtedly have an important bearing on the solution of some geochemical problems

THE seventh annual number of *Brighter Biochemistry*, the journal of the Cambridge Biochemical Laboratory, is up to the standard of its predecessors The identity of the various contributors is but thinly veiled under the initials appended to each item For matter, the authors have cast their net wide and caught a number of well known scientific workers whose habitat is not in this laboratory The number could scarcely have been considered complete without references to the Nobel prizemen for 1929 It is probable that for a true appreciation of many of the points a personal acquaintance with the victims and their biographers is a necessary precedent, but even without this knowledge many of the rhymes can be understood by those with some idea of modern biochemical literature For an hour's quiet fun, the number can be recommended to all biochemists and physiologists as a method of retreat from scientific problems

THE successor to the ninth annual report of the Tidal Institute of the University of Liverpool is the Annual Report (1929) of the Liverpool Observatory and Tidal Institute, which now form a single institution governed by a joint committee of the Mersey Docks and Harbour Board, and the University of Liverpool The scientific staff numbers Prof J Proudman and Dr A T Doodson, as director and

associate director, with six assistants About half the income of the institution is derived from grants by the Board, the University, and the Liverpool Steam Ship Owners' Association, the remainder being obtained as payment for services rendered by the institution to outside bodies, these services consist mainly of the analysis and prediction of tides, but also of the supply of meteorological information and the testing of chronometers, sextants, and other instruments The institution has acquired the business, and the tide predicting machine, of Messrs E Roberts and Sons, Broadstairs, tidal and astronomical computers, the first machine owned by the institution was being worked almost to its full capacity The detailed account of the year's activities shows that the institution continues its valuable and highly successful combined work of practical analysis and prediction of tides, with theoretical research on tidal currents and the meteorological and other influences which affect them

IT has long been known that the currents in the mains of electric traction systems interfere, sometimes most seriously, with delicate electrical measurements carried out in laboratories and observatories It has now been proved that similar interference from electric tramways has been affecting the quality of the reception in broadcast receiving sets Some results obtained by C O Horn of the Post Office are published in *Engineering* for Feb 21 Generally, in electric tramways in Great Britain, a trolley wheel is pressed against the trolley wire At every suspension 'ear', the trolley usually gives a jump, the ensuing arc burning by a minute amount the wheel and the wire Similarly, at the section insulators which occur at every half-mile, there is an arc when the wheel passes from one section to the next Radio receiving sets in the neighbourhood hear a click every time an arc is formed Tests made at Blackpool prove that if the trolley wheel be replaced by a Fischer plate similar to those usually employed on the continent, much of the noise is eliminated Tests were made at Birmingham with another type of collector, but the results were not so good as those obtained by the Fischer plate It was apparent that most of the interference was due to causes outside the collecting system Satisfactory results were obtained by transposing the coils of the traction motor so that they came between the trolley wire and the armature instead of between the armature and the rails. In the new position, the coils act as a high frequency choking coil and so prevent the formation of oscillatory currents

THE nineteenth report of the Development Commissioners for the year ending Mar 31, 1929, has recently been published by H M Stationery Office It is arranged in four sections, the first two of which are concerned with advances in agriculture, rural economy, fisheries, and harbours The third part relates to action taken in connexion with the compulsory acquisition of land for road improvement, while the fourth deals with the financial position of the Development Fund The successful establishment of the eight new Imperial agricultural bureaux was one of the chief features of the year, their object being to act as central agencies for the collection and dissemination of information on the various branches of agricultural research An important step in determining the practicability of extending electrification into rural areas has been taken in a trial scheme started in Bedfordshire, from which it is hoped to calculate the probabilities of success in other areas With regard to research and education, each of the institutes and advisory centres is dealt with in turn and an account of the investigations in progress given in some detail In the rural economy section, the work of the community councils and their organisation for the development of rural industries seems to be giving encouraging results Reports are also supplied of the work at the various marine biological institutions and of the special investigations 'directed' by the fishery departments of the Ministry The grants and loans made during the year are quoted in detail, and the report concludes with three appendices, in which a list of all work published by members of the staffs of institutions receiving financial support from the fund is given

THE honorary membership of the Academia Scientiarum Fennica, Helsingfors, has been conferred on Sir J C Bose for his contributions in advancement of knowledge of life reactions in plants

THE G J Symons memorial lecture of the Royal Meteorological Society will be delivered on Mar 19 by Dr Herbert Lapworth, who will take as his subject, "Meteorology and Water Supply"

THE following appointments in the Colonial Agricultural Services have recently been made by the Secretary of State for the Colonies Dr W, Youngman to be director of agriculture, Ceylon, Mr E J Wortley, director of agriculture, Nyasaland, to be director of agriculture, Trinidad, Mr F Burnett, divisional agricultural officer, Ceylon, to be deputy director of agriculture, British Guiana, Dr F J Martin, agricultural chemist, Sierra Leone, to be assistant director of agriculture, Sierra Leone, and Mr R W Donkin to be produce inspector, Nigeria

THE governors of the Scottish Woollen Technical College, Galashiels, have elected Dr A W Stevenson, of the British Research Association for the Woollen and Worsted Industries, as colleague and successor to Dr Thos Oliver, who wishes to retire from the principalship in 1931 Under Dr Oliver, wool textile education in Galashiels has grown from a local evening class to a well equipped mono technical institution controlled by and serving the whole Scottish woollen industry He was also a pioneer in wool textile research, that being the subject of his degree thesis more than twenty years ago Since the war, Dr Stevenson's principal work has been connected with problems in worsted spinning The high standard of this work was recognised by the University of Edinburgh in 1928, when the degree of Doctor of Science was awarded to him on a comprehensive thesis embodying the main points of his investigations

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A senior secretary in the Matriculation and School Examinations Department of the University of London—The

Principal, University of London, South Kensington, S W 7 (Mar 22) Examiners in the following subjects for the Matriculation Examination of the University of London for 1931 Chemistry, French, Geography, German, Latin, Modern History, Physics, Spanish—The Secretary of the Matriculation and School Examinations Council, University of London, South Kensington, S W 7 (Mar 27) A professor of pathology and bacteriology at the Calcutta School of Tropical Medicine—The Secretary to the High Commissioner for India, Education Department, India House, Aldwych, W C 2 (Mar 27) A chief sanitary officer for the Asansal Mining Settlement under the Asansal Mines Board of Health, Burdwan District, Bengal—The Secretary to the High Commissioner for India, General Department, India House, Aldwych, W C 2 (Mar 29) An assistant horticultural instructor at the Hertfordshire Agricultural Institute, Oaklands, near St Albans—The Clerk of the County Council, 28 Castle Street, Hertford (Mar 29) A woman lecturer in biology at the Avery Hill Training College, Eltham—The Education Officer (H 2/1), County Hall, Westminster Bridge, S E 1 (Mar 31) A Bernard Baron research student in the Ferens Institute of Otolaryngology of Middlesex Hospital—The Secretary, Middlesex Hospital Medical School, W 1 (April 7) A professor of physiology at Bedford College for Women—The Academic Registrar, University of London, South Kensington, S W 7 (April 15) A lecturer in the chemistry of cellulose at the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (April 21) A woman assistant lecturer and demonstrator in botany at the Royal Holloway College—The Principal, Royal Holloway College, Englefield Green, Surrey (April 24) A whole time medical registrar for the Society of Apothecaries of London—The Clerk, Apothecaries Hall, Water Lane, Blackfriars, E C (April 30) A director of the Institute of Plant Industry, Indore and Agricultural Adviser to States in Central India and Rajputana—The Secretary to the Board of Governors, Institute of Plant Industry, Indore, India (Aug 31) An assistant master (a graduate in engineering with emphasis on electrical engineering) in the Junior Technical School of the Maidstone Technical Institute, and for evening classes—The Principal, Technical Institute Maidstone An assistant secretary of the British Association for the Advancement of Science—The Secretary, British Association, Burlington House W 1

Our Astronomical Column

Comets—*Popular Astronomy* for February contains a photograph by Prof G van Biesbroeck of Wilk's comet taken on Dec 31, 1929 The tail extends as a narrow ribbon to the edge of the plate 1° 36 from the nucleus There are fainter tails, about 40′ long, on each side of it There is a bright circular coma, some 4′ in diameter, with a fainter border On Jan 22 the tail lagged 5° or 6° behind the prolongation of the line from the sun to the comet

Prof van Biesbroeck is still observing two other faint comets, 1927 IV, Stearns, the magnitude of which is now 16, and 1925 II, Schwassmann Wachmann (1) A photograph on Dec 28 showed it as a circular nebulosity 1′ in diameter with a brighter central condensation 20″ in diameter Its magnitude was 15 A visual observation with the 40 inch refractor on Dec 30 gave a diameter of 25″, the faint outer border being invisible to the eye

Saturn—*L'Astronomie* for January contains an illustrated article on Saturn by M E M Antoniadi Most of the drawings were made by him with the great Meudon refractor between 1927 and 1929, but a few older ones are reproduced Stress is laid on the dusky polar caps, the author concludes that the irradiation produced by the brighter regions between the poles and the temperate zones causes them to appear to bulge out beyond the elliptical outline and so produce the 'square shouldered aspect' noted by Sir William Herschel and by many later observers Drawings made in July and August 1927 show some spots, both bright and dusky, breaking the regularity of the belts, some of these look definite enough to use for obtaining values of the rotation period, of which there are not very many determinations, this question is not, however, discussed in the article It is noted that these markings are much less permanent than on Jupiter, where the Great Red Spot has now persisted more or less visible for half a century

Plans for the 200-Inch Telescope—The *Scientific Monthly* for January contains an article by Dr Elihu Thomson on the plans and experiments that are now in progress with regard to this proposed gigantic telescope The use of glass for the great mirror is considered impracticable, hopes are entertained that fused quartz will prove suitable, one great advantage is the much smaller coefficient of expansion Dr Thomson describes some experiments on a small scale in which mirrors of glass and quartz were compared, the image of an artificial star was almost instantly shattered on applying heat to the back of the glass mirror, the quartz one reached a much higher temperature before the image was much distorted The main body of the proposed great mirror would be formed by fusing a great mass of quartz sand in an electric furnace at a temperature of 1700° 1800° C This would contain bubbles on cooling, but it is not considered that these would do much harm On this block a surface of clear glass like fused quartz, or silica glass, would be deposited A method of doing this has been arrived at, a quantity of finely powdered crystal quartz is poured through a very hot oxy hydrogen jet, which melts it It falls in this state on the face of the mirror, where it solidifies in a transparent deposit The process is compared to the deposit of clear ice on objects during a sleet storm Small mirrors have already been successfully made, and some of these may be of use as the subsidiary mirrors which will be required in the proposed telescope It is thought that at least three years will be necessary for the production of the great mirror, even before the figuring begins There will be the advantage in the figuring that the heat produced by friction will not distort the figure so much as in the case of glass, in that case, frequent pauses have to be made to allow the glass to cool Dr Thomson states that the General Electric Company at West Lynn has offered to make the mirror merely at the cost of the labour and material

Research Items

Cultural Areas in Africa.—In *Africa* for January, Dr. Melville J. Herskovits applies to the ethnological problems of Africa the American method of 'cultural areas'. He suggests nine cultural areas: (1) Hottentot: essentially a herding culture but differing from the Bantu, in that there is no agriculture, and the women have much to do with the herds. The cattle are given as gifts in marriage, but for the wedding feast, not as a dower. The language, with that of the Bushmen, is differentiated by the 'click'. (2) The Bushman: with poor material culture, but high artistic and literary (folklore) ability. The dog is the only domesticated animal, and hunting is brought to a high degree of skill. (3) The East African cattle area: cattle determine a man's position and prestige, and are utilised in all the important ceremonials of life; but they do not furnish food, excepting milk, or when eaten as a ceremonial offering or after they have died. Food is obtained from the produce of the fields, and is the work of the women, to whom the care of the cattle is forbidden. Polygamy prevails, being based on the number of cattle a man commands. (4) The Congo: predominantly agricultural. The people live in rectangular houses, make bark cloth, use masks, practice cicatrisation, and carve human representations. The secret society is important. (5) The East Horn: not sharply differentiated, but shades off from East Africa. The camel and horse slowly take the place of cattle—a marginal area. (6) The eastern Sudan: a nomadic culture organised around live stock. Living in a hard desert area, their first care is the feeding and watering of their animals. The religion is Mahommedanism and the social order is strongly paternal. Clothing is of cloth and the people live in tents. (7) The western Sudan: a marginal area, in which great kingdoms—Benin, Bornu, Haussa—have risen. The economic life is basically herding, agriculture, and trade. (8) Desert: a nomadic area dependent upon trade, camel and horse breeding. (9) Egypt: an area distinct from the rest of Africa, of which the influence on other African culture must have been profound.

Preservation of Fruit and Vegetables.—One of the difficulties in the fruit and vegetable trade is the tendency for periods of scarcity to alternate with seasons of plenty when the market may be glutted with perishable produce, which must be sold at once or thrown away. In such a case the preservation of the surplus for future sale prevents instability of the market and presents the consumer with a constant source of supply of perfectly satisfactory foods, containing all the food values of the fresh materials and often many of the vitamins as well. At the request of the Ministry of Agriculture and Fisheries, the workers at the University of Bristol Research Station, Campden, have compiled a short monograph on the subject of the domestic preservation of fruit and vegetables (Ministry of Agriculture and Fisheries Miscellaneous Publications, No. 69, "Domestic Preservation of Fruit and Vegetables". London: H.M. Stationery Office, 1929. 1*s*. net). After a short chapter on the theory of preservation, practical details, including numerous recipes, are given for fruit canning and fruit bottling, for jam making, for the preparation of fruit jellies and syrups, and of candied, crystallised, and glacé fruits, for the preservation of vegetables, the drying of fruit and vegetables, and the preparation of chutneys and pickles. Many of the recipes given are based on those which have been in use in domestic households for many generations. The methods described can be used by the housewife or by the manufacturer.

Artificial Ripening of Bananas.—Bananas for export are gathered unripe and their proper maturation afterwards is an important commercial problem, investigations upon which have been undertaken by the Australian Council for Scientific and Industrial Research (*Jour. for Sci. and Indust. Res.*, Commonwealth of Australia, vol. 2, 1929, p. 219). It is recommended that at first the store should not be ventilated, though its air should be kept in motion by a fan, and a temperature of 68° F. and a relative humidity of 85-90 per cent maintained. An addition of coal gas night and morning, in the proportion of one part to 2000 parts of air, is found to accelerate the ripening and to produce more uniform ripening throughout the bunch, probably by means of its ethylene content.

Methods of Tagging Fishes and Crustacea.—With the view of tracing the migratory habits of commercial fishes and the Cape crawfish (*Jasus lalandii*), Dr. Cecil von Bonde (*Fisheries and Marine Biological Survey*. Report No. 6. For the Year 1927–1928. Special Report No. 2. Pp. 1-7 and No. 3. Pp. 1-5) has made use of aluminium tags fixed to the upper lobe of the caudal fin, covering the base of the caudal rays, and finds that these function quite effectively. They are fixed to the fish by means of a pair of tongs, which are figured. He also suggests that there is reason to suspect the spawning ground of the South African eels to be in the deep waters of the Indian Ocean. The difficulty of marking Crustacea, which undergo periodic ecdysis, is overcome by attaching aluminium tags through the ventral flexor muscles lateral to the mid-ventral line, thus avoiding the nerve cord and the blood vessels. Preliminary tests of this method have been successful.

Pycnogonida of South Africa.—Prof. Thomson Flynn has described the important forms obtained from South African waters (Fisheries and Marine Biological Survey. Report No. 6. For the Year 1927–28. Special Report No. 1. Pp. 1-36. The Government Printing and Stationery Office, Pretoria, 1928). Of nineteen species examined, only nine had been described previously. The new species *Nymphon bipunctatum*, *N. natalense*, *N. comes*, *Parapalene calmani*, *Pallenopsis intermedia*, *Pseudopallene gilchristi*, *Anoplodactylus pelagicus*, *Phoxichilidium capense*, *Pycnogonum forte*, and *Tanystylum ornatum* are figured and described. It is interesting to note that as many as thirty-five specimens comprising four species have been captured by a tow-net off Port Natal and that "all the species are of slender fragile type with long limbs, such as may be expected to be good swimmers". *Pallenopsis ovalis*, which has been recorded by Loman from the East Indies, by Calman from the Andamans and from Ceylon, and *Parapallene nierstraszi* by Loman from the East Indies, were obtained from the west and south-west coasts, thus suggesting an obvious relationship between the Pycnogonid fauna of South Africa and the East Indies. This is probably due to the course of the equatorial current, which also exists on the east coast of Australia.

Earth Evolution.—The *Journal* of the Washington Academy of Sciences, vol. 20, pp. 17-25, Jan. 18, 1930, contains an interesting article by B. Gutenberg on "Hypotheses on the Development of the Earth". The ideas involved are to be more fully explained and developed in a future volume (3) of the "Handbuch der Geophysik". He accepts Darwin's theory of the evolution of the moon by fissure from the earth, and supposes that whereas, before this event, the earth's

crust was nearly in hydrostatic equilibrium, afterwards the outer sialic shell was absent from the part whence the moon was removed, so that the hydrostatic equilibrium was completely disturbed In the Carboniferous epoch, some degree of quiet seems to have been restored, but at this time nearly the whole complex of continents was a single block situated in the southern hemisphere Under the action of hydrostatic forces, this block separated into pieces which began to drift apart, and do so even to day, at the same time, the *Polflucht* forces tended to move the whole mass so that about equal parts lay on the two sides of the equator This having been accomplished, no further large movement of this block as a whole is to be expected, though the continents will continue to spread out and the surface of the extending regions will tend to sink, as is perhaps exemplified in the sinking of the western coast of Europe

Collisions between Very Slow Electrons and Molecules—In two recent papers in the *Annalen der Physik* (vol 3, p 536, and vol 4, p 91) C Ramsauer and R Kollath have given an account of some new work upon the collisions of very slow electrons with gaseous atoms and molecules Using the original form of apparatus devised by Ramsauer, they have now been able to study the motion of the electrons for speeds equivalent to a fall of potential of only one sixth of a volt Their results again show a dissimilarity between the behaviour of different gases Amongst the inert gases, the effective area of helium changes little with the speed of the incident electron, whilst the area of neon decreases continually with fall in electron velocity Argon, krypton, and xenon, on the other hand, have a single minimum in the area velocity curves, a property shared by oxygen and by methane The curves for nitrogen and the oxides of carbon are more complicated The maxima and minima on these curves occur in general at potentials which are far below the critical potentials of the gases, the small irregularities on the curve for helium, for example, being at about one volt, whilst its lowest excitation potential is just below twenty volts The authors suggest that the area velocity curves for all gases may be found to have a minimum even where this has not already been found, when the great technical difficulties in the way of working with electron speeds less than 0 16 volt can be overcome

Extreme Ultra-Violet Spectra—Further details of the important work of B Edlén and A Ericson on extreme ultra violet spark spectra (see NATURE, Nov 2, 1929, vol 124, p 688) are given in the *Zeitschrift für Physik* for Jan 21 The spectrograph designed for this purpose by Prof Siegbahn is relatively simple in construction, the spark chamber being a modified Siegbahn metal X-ray tube exhausted from one lead of a pump, the other lead from which evacuated the main chamber of the instrument The grating used had a radius of curvature of 101 cm, and was ruled over an area of 35×50 mm^2, the ruling being performed at the National Physical Laboratory, Teddington The plates used for photographing the spectra were Schumann plates with glass only 0 4 mm, in thickness, these being considered preferable to several other types of plates and films that were tested More reproductions of spectra are given than were shown in NATURE, perhaps the most interesting of which are enlargements of two multiplets at 834 A and 1175 A taken in the first order, which show very well the detail which can be recorded, the two lines at 832 75 A and 832 92 A being clearly separated A note added in proof states that it has now been found possible by the use of a more intense spark as source to push the limit of the spectra still farther into the ultra violet (see NATURE, Feb 15, 1930, p 233) The first members of the hydrogen like spectra of doubly ionised lithium (Li III) and of trebly ionised beryllium (Be IV) have been found at 135 02 A and 75 94 A respectively, and considerable extensions of the spectra of doubly ionised beryllium (Be III) and of the third, fourth, and fifth spark spectra of aluminium have also been made in the same region

Oxides of Nickel—Measurements of the heats of solution in sulphuric acid of nickel hydroxide and of its various oxidation products, the results of which are given by Giordani and Mattias in the *Rendiconti dell' Accademia delle Scienze Fisiche e Matematiche di Napoli* (1929), indicate the existence, between NiO and Ni_2O, of two intermediate oxides Of these, the one with the higher content of active oxygen determines the characteristic potential of the anode during the greater part of the discharge of the alkaline accumulator

Respiration Apparatus—This assembly of apparatus for indirect calorimetry, designed by Dr E Simonson, of Frankfort a M and manufactured by Askania Werke A G, of Berlin Friedenan (London agent, O G Karlowa, Abford House, Victoria, S W 1), differs but slightly from existing models such as the Douglas Haldane equipment A diverting manifold (see Fig 1 8 12) is attached directly to the mouth

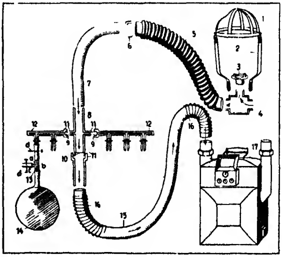

FIG 1

piece (4), permitting of the sampling of expired air for analysis in either a rubber or cellophane bag (14), while the volume of expired air is obtained from the dry meter (17) A variety of orifice plates with packing rings (9) are available with capillary metal tubes which can be closed individually, thus enabling the removal of short or continuous samples (about 1 litre) of the expired air in a protracted experiment The volumes per unit time of these samples, naturally, will depend on the cross sectional areas of the orifices, which are always predetermined It thus becomes possible to withdraw samples for analysis at any stage of the experiment and to measure the basal metabolic rate before and after the experiment The diverting manifold is obtainable in a portable form for strapping on the back and weighs about 2½ lb The apparatus may find application in experiments of long duration where the more expensive chambers or closed circuit assembly are at present used

Recent Work on Vitamin A

DURING the past two years advances have been made in our knowledge of the chemistry and properties of vitamin A and its relationship to certain other compounds, but progress, though steady, has not been so dramatic as in the case of vitamin D Attention has been directed chiefly to methods of assay, both biological and chemical, to attempts at isolation of the vitamin, and to its formation under natural conditions less work has been devoted to its physiological functions In this article certain aspects of the subject will be briefly reviewed

ASSAY

The tediousness and inherent difficulties of the biological test have led investigators to seek some simple chemical reaction or some physical property which could be utilised for the quantitative determination of the vitamin However, since these methods are not absolutely specific, the final criterion must be the animal test, so that its accuracy has been critically considered and its technique improved, in the hope of obtaining more reliable results

The arsenic trichloride test of Rosenheim and Drummond (*Biochem J*, vol 19, p 753, 1925) and the antimony trichloride test of Carr and Price (*ibid*, vol 20, p 497, 1926) have been widely used, more especially the latter, since the blue colour produced lasts somewhat longer than that given by the former reagent Certain precautions have to be observed in carrying out the test, since the proportionality between the amount of vitamin A containing oil taken and the blue colour developed is not linear except possibly over a small range of concentrations It is necessary, therefore, to find the amount of oil which will give a standard depth of colour, since the blue is usually mixed with other colours, it is most conveniently measured in Lovibond tintometer units It is also essential to standardise the reagents and the temperature the amount of oil present influences both the rate of development and of fading of the colour (N Evers, *Quart J Pharmacy and Pharmacol*, vol 2, p 227, 1929 T T Cocking, *ibid*, p 310 E R Norris and I S Danielson, *J Biol Chem*, vol 83, p 469, 1929) With cod liver oil, good agreement has been obtained between the colorimetric and biological methods, but the presence in animal fats of other substances giving the blue colour with antimony trichloride interferes with the direct quantitative estimation of the vitamin Thus both carotin and xanthophyll give a deep permanent blue under the conditions of the test Willimott and Wokes (*Lancet*, vol 2, p 8, 1927) removed the interfering pigments by adsorption on charcoal, and found good agreement between the two methods of assay in the case of a variety of vegetable and animal foodstuffs The blue colour can be distinguished also by spectroscopic examination thus in the case of vitamin A with the $AsCl_3$ reagent, there is a band at 5870 A, with a second band, developing on standing, at 4750 A, with the $SbCl_3$ reagent the initial band is at 6140 A and the second at 5300 A in both cases the initial bands rapidly fade Carotin, however, gives a band at 5900 A and the colour produced is duller and greener (Rosenheim and Drummond, loc cit, Wokes, *Biochem J*, vol 22, p 997, 1928 Moore, *Lancet*, vol 2, p 219, 1929) Blue colours are also given by other compounds, but under conditions in which they are not likely to be confused with that given by vitamin A thus both cholesterol and cholic acid, after treatment with benzoyl chloride in solution in chloroform, give a blue colour with $AsCl_3$ (Rosenheim, *Biochem J*, vol 21, p 386, 1927 Wokes, *ibid*, vol 22, p 830, 1928) The cholesterol oxidation product has none of the properties of vitamin A, fails to give the colour after solution in oil, and has no stimulating effect on growth

The absorption spectrum of cod liver oil shows bands at 3200 3280 A and 2700 2900 A Morton and Heilbron (*Biochem J*, vol 22, p 987, 1928) have found that the intensity of the former band varies with the intensity of the blue colour developed in the $SbCl_3$ test, both in natural oils and concentrates, and also in oils oxidised or irradiated when the band disappears and no blue colour is obtained Other compounds may show a band near 3200 A their presence is disclosed after oxidation of the oil Although the intensity of this band may, under certain conditions, be used as an estimate of the concentration of vitamin A in the oil, yet it is not absolutely specific for the vitamin, so that it cannot be relied on as sole test, without an accompanying biological assay, in the case of materials from which the presence of interfering substances has not been excluded Rosenheim and Webster (*ibid*, vol 23, p 633, 1929) have, in fact, shown that dehydroergosterol has an absorption band at 3200 3280 A, but gives no blue colour with $AsCl_3$ or $SbCl_3$, and is inactive in doses up to 1 mgm per diem when given to rats maintained on the standard deficient diet The intensity of the band, however, is considerably less than that of the absorbing substance in cod liver oil

A number of workers have analysed the responses of their animals, the growth of which had ceased on a vitamin A deficient diet, to various supplements containing the vitamin It is now agreed that such a diet must contain vitamin D, and that results obtained on diets deficient in both vitamins A and D cannot be relied on to give even a rough idea of the vitamin A activity One of the difficulties of the usual method of assay is that when growth ceases the rat is frequently suffering from some infection, and that a supply of vitamin A may fail to stimulate growth until the infection has cleared up, or if the dose is too small, the animal may succumb to its infection Coward and Key (*ibid*, vol 22, p 1019, 1928) find that the responses of depleted animals fall into four groups there may be no response, on too small a dose, there may be subnormal quantitative growth, with or without premature slackening, on a small dose, or there may be normal growth, with premature slackening or to maturity, according to the size of the dose given Sometimes a growth response only occurs after a latent period of some weeks They consider it necessary to use 2 4 animals on each dose with a test period of 8 weeks Hume and Smith (*ibid*, vol 22, p 504, 1928) report similar results they are of opinion that it is possible to obtain a qualitative result by this method, and possibly in the first 3 4 weeks of vitamin A feeding after a depletion period, to attain a quantitative assay They consider that a better method is to give the animals small doses of vitamin from the beginning of the experiment the growth curves are graded according to the size of the dose, but a result cannot be looked for in under 3 months

Drummond and Morton (*ibid*, vol 23, p 785, 1929) found the growth responses of different animals on the same doses to vary considerably up to twelve animals on each dose, with an extensive range of doses, must be used to obtain a distinction between two cod-liver oils differing from each other by less than 100 per cent Only the growth rates for the first 5-6 weeks following the depletion period should be considered better results are obtained when doses necessary to give a growth rate of 3 grams per week

are compared than when comparison is made between rates of growth on the same dose These authors hold, however, that for quantitative estimation of vitamin A in cod liver oil, the colour test or the determination of the intensity of the absorption band gives more reliable results than the biological assay Similar analyses have been published by Nelson and Jones, and Sherman and Burtis (*J Biol Chem*, vol 80, p 215, and vol 78, p 671, 1928) Smedley Maclean and her co workers (*Biochem J*, vol 23, p 634, 1929) suggest that doses of the substance under test which will just sustain life over a certain time, and those which just fail to do so, should be determined, since a better comparison between different samples can be made thus Furthermore, as a check upon the response of the animal, a dose of cod liver oil which might be expected to stimulate growth should be given at the end of the experiment

In connexion with biological assays, some recent work by Coward and her collaborators may be referred to (Coward *et al*, *Biochem J*, vol 23, pp 695 and 913, 1929) Rats sometimes fail to grow on an apparently complete synthetic diet, the failure has been traced to the casein employed, since changing the casein permits of normal growth This work may explain some of the irregular results which are observed at different times in vitamin A (and B) assay

CHEMISTRY

Drummond and Baker (*Biochem J*, vol 23, p 274, 1929) have investigated the chemical nature of vitamin A Unsaponifiable matter was prepared from the liver oils of the cod, sheep, and Greenland and Japanese sharks Cholesterol was removed by crystallisation only small amounts were present in the shark liver oils, the chief constituents being selachyl, batyl, chimyl, and oleyl alcohols, some of which were removed in part by crystallisation from suitable solvents The residual oils were then submitted to fractional distillation at very low pressures no satisfactory fractionation was obtained in the case of cod or sheep liver oils, and in both cases decomposition occurred recovery of the vitamin from the fractions was only 2 and 11 per cent respectively, as estimated by the colour test Distillation of the shark liver oils yielded only the higher alcohols, but the vitamin recovery was up to 50 per cent in the case of the Japanese shark liver oil It is considered that the destruction of the vitamin in the former case is due to the presence of complex alcohols and hydrocarbons of the terpene series, which are only present in small proportions in the shark oils No fraction consisting exclusively of vitamin A was obtained, nor was it separated by crystallisation It appears that it is present in Japanese shark liver oil to the extent of 1 per cent only, or less, of the unsaponifiable matter The authors are of opinion that it is probably a sterol, from the nature of its colour reactions, and suggest that its chemical composition may be elucidated rather by studying the properties of sterols than by attempting its isolation from a natural source

In connexion with the destruction occurring on distillation at low pressures, it may be mentioned that Wokes and Willimott (*ibid*, vol 21, p 419, 1927) suggest, as a result of experiments on the effect of heat and oxidation on the vitamin A content of cod liver oil, that the destruction observed may be due to the presence of volatile organic peroxides

In the identification of the complex alcohols present in liver oils, it is often necessary to hydrogenate the material and isolate the reduced products Drummond and Baker (loc cit) found that reduction of the oil obtained from the unsaponifiable matter of cod-liver oil, after removal of sterols by digitonin, did not destroy completely the vitamin A content, but the reduction was admittedly incomplete Nakamiya and Kawakami (*Sci Papers, Inst Physical and Chem Res*, vol 7, p 121, 1927), however, found that hydrogenation of 'Biosterin' led to complete loss of the vitamin activity

Another line of approach to the chemical nature of vitamin A has been the study of its relationship to certain plant pigments Xanthophyll has been shown to have no growth promoting power (Willimott and Moore, *Biochem J*, vol 21, p 86, 1927 Smedley Maclean *et al*, *ibid* vol 23, p 634, 1929), but several observers (v Euler, Maclean, Moore) have found that carotin in very small doses can restore normal growth in a rat maintained on a vitamin A deficient diet

Collison, Hume, Smedley Maclean, and Smith (*Biochem J*, vol 23, p 634) have investigated the nature of the vitamin A constituent of certain green leaves The material soluble in light petroleum was extracted from green cabbage and saponified the yield was 0 84 per cent of the dried leaves The unsaponifiable matter was fractionated by means of solvents cold alcohol extracted a sterol together with a substance giving the blue colour with antimony trichloride hot alcohol extracted from the residue nonacosane and di *n* tetradecyl ketone whilst from the final material carotin was obtained by extraction with light petroleum the carotin had definite growth promoting power even in a daily dose of 0 003 mgm From white cabbage little carotin was obtained, and this material contained little vitamin A Carotin prepared from spinach and carrots was also active, in doses of 0 01 mgm daily, but it was obtained in a somewhat less pure condition than when cabbage was used as source The authors consider that possibly more than one substance can function as vitamin A, that, in fact, the growth promoting power is the property of a special grouping of atoms which may occur in several different molecules they cite the observations of v Euler and his co workers, who have shown that dihydro α crocetin is also active Moreover, the absorption spectra of the blue colours produced by vitamin A and carotin with $SbCl_3$ are different, but no trace of the former appears in that of an active sample of carotin, suggesting that vitamin A is not simply a contaminant of the latter It is possible that the negative results of Drummond as regards the potency of carotin are due to the fact that his basal diet is free from fat There is evidence that some constituent of the unsaponifiable fraction of the fat is necessary for carotin to exert its growth promoting power

Moore has also found that carotin can exert a vitamin A activity (*Biochem J*, vol 23, p 803, 1929 *Lancet*, vol 2, p 380, 1929) His results confirm those obtained by other workers, who have found carotin active, but his latest experiments have led to a different conclusion Carotin was fed to rats in daily doses of from 0 0001 to 0 75 mgm, after 5 weeks the animals were killed the fat extracted from the liver and analysed for vitamin A by colorimetric and spectroscopic methods The intensity of the vitamin A blue reaction (absorption band at 6100 6300 A) indicated that a daily dose of 0 01 mgm or more of carotin increased the vitamin A content of the liver at the same time only a very slight increase in the degree of yellow pigmentation of the fat occurred, showing that carotin was stored to only a negligible extent in this organ Hence, even when a large excess is ingested, carotin appears in the liver only in minute traces, the simplest explanation of the increase in the vitamin A content is that it was actually formed from a portion of the carotin eaten

In a recent review Drummond points out that the

ordinary standards of chemical purity give insufficient security in biochemical work with substances so highly active as the vitamins (*Chem and Industry*, vol 49, p 1 T, 1930) The difficulties experienced in detecting ergosterol as the impurity in cholesterol which is activated by exposure to ultra violet light need scarcely be referred to in this connexion In this case, the doubt is as to the purity of the carotin used by the various investigators who have found it to contain growth promoting activity Drummond has obtained carotin of melting point so high as 185° it showed no vitamin A activity even in relatively large doses He has also prepared di hydro-α crocetin his specimen failed to restore growth in rats deprived of vitamin A From the results obtained with liver oils, it may be estimated that the daily dose of the vitamin for a rat is probably less than 0 0001 mgm , an order of activity comparable with that of vitamin D If this is so, preparations of vitamin A which must be given in larger doses to restore growth must necessarily be impure

PHYSIOLOGY

The presence of vitamin A in the diet is essential if it is to be adequate for growth and the maintenance of normal health E Mellanby has stressed the latter function without vitamin A in the food, infections occur regularly among the experimental animals administration of large quantities to human beings may cure certain infections (see NATURE, vol 122, p 750, 1928) It must be assumed that vitamin A is, or is the precursor of, an essential constituent of certain cells of the body without it they can neither multiply nor maintain their normal structure In many cases the onset of an infection appears to be facilitated by an alteration in the cells lining an exposed surface when the vitamin is withdrawn from the diet

Unlike vitamin D, vitamin A is not synthesised in the animal body hence it is important to see that it is present in the food Thus the content of cow's milk in this vitamin depends on the food given the animal, it is increased by feeding green food and cod liver oil The vitamin D in the milk can be increased by giving it in the food or by irradiating the cow or even the milk itself

Yeast, a source of many interesting compounds, does not contain vitamin A previous conclusions to the contrary were the result of using a diet deficient in both vitamins A and D in testing for this vitamin (Hume, Smith, and Smedley Maclean, *Biochem J*, vol 22, p 27, 1928)

The ultimate source of vitamin A is the green plant there has been considerable doubt as to whether the presence of light is necessary for its formation or not, partly owing to the difficulty of excluding all light, partly owing to the fact that many tests have been carried out using a basal diet deficient in both vitamins A and D The most recent work indicates, however, that vitamin A can be formed in the complete absence of light, except the minimum required to feed and handle the animals and collect the etiolated shoots Moore found that wheat seeds contained no vitamin A, that etiolated shoots fed to rats in a diet containing vitamin D but no A stimulated growth, although given to the animals after dark, and finally that the same result was obtained when no light except red was admitted to the room in which the animals were housed and the shoots grown throughout the experiment (*ibid*, vol 21, p 870, 1927, vol 22, p 1097, 1928) It is, however, possible that the brief exposure to the red light may have been the essential factor in the production of the vitamin it is certain that light can accelerate the synthesis, since green plant tissues are better sources than white

Education and Science in the Civil Service Estimates

THE Civil Estimates and Estimates for Revenue Departments (Vote on Account) for the year ending Mar 31, 1931, have been issued (82 London H M Stationery Office 3*d* net) The total of the estimates for the full year is £368,095,208, against a total of £320,190,105 voted for the current year, this latter total, however, includes supplementary estimates

The items in which readers of NATURE will be most interested occur in Classes IV and VI, and are as follows

	Total Estimate for 1930 (Net)	Total Net Estimate for 1929 (adjusted for transfers)
Class IV		
Board of Education	£45,495,653	£41,685,899
British Museum	297,263	283,559
Scientific Investigation, etc	232,303	228,278
Universities and Colleges, Great Britain	1,830,000	1 550,000
SCOTLAND		
Public Education	7,197,422	6,173,485
Class VI		
Ministry of Agriculture and Fisheries	2,312 310	2,953,863
Beet Sugar Subsidy, Great Britain	5,400,000	4,250 000
Surveys of Great Britain	143,203	140,980
Forestry Commission	837,800	600,000
Development Fund	625,000	300,000
Development Grants	200,000	—
Department of Scientific and Industrial Research	469,278	446,214
SCOTLAND		
Department of Agriculture	574,918	484,047
Fishery Board	137,442	68,895

The details of Class IV estimates are now available (83 IV London H M S O 1*s* 3*d* net) Under the heading "Scientific Investigation, etc", there is an increase of £4025 over last year's estimate The position is shown in the following table

GRANTS IN AID	1930	1929	Increase
Royal Society	£10,000	£10,000	—
Royal Geographical Society	1,250	1,250	—
Royal Society of Edinburgh	600	600	—
British School at Athens	500	500	—
British School at Rome	500	500	—
Royal Scottish Geographical Society	200	200	—
National Library of Wales	25,334	25,333	£ 1
National Museum of Wales	28,000	27,000	1,000
Solar Physics Observatory	3,000	3,000	—
North Sea Fisheries Investigation	1,150	1,150	—
Royal Academy of Music	500	500	—
Royal College of Music	500	500	—
Royal Academy of Dramatic Art	500	500	—
British Academy	2,000	2,000	—
Central Library for Students	3,000	—	3,000
Medical Research Council	148,000	148,000	—
OTHER GRANTS			
Edinburgh Observatory	7,269	7,245	24
	£232,303	228,278	4,025

Under the heading "Universities and Colleges, Great Britain", there is an increase of £280,000, the greater part of which, £243,110, is put down as unallocated grant

The detailed estimates for Class VI, departments dealing with trade and industry, have also been issued (83-VI London H M S O 3s net) From these it appears that grants for agricultural education and research are increased on those of the current financial year by £165,410, the largest parts of which are £93,400 for agricultural education and £67,760 for grants for research The Fisheries Department estimate shows an increase of £87,519, this is largely accounted for by the provision of £80,000 for the construction of a new vessel for deep sea research and investigation

The estimates for the Forestry Commission show a net increase of £101,800, a large item here is the increase of £29,840 under the heading of forestry operations, the greater part of which is for the acquisition of land, buildings, and standing timber

The Department of Scientific and Industrial Research estimate shows a net increase of £23,064 over that for the current year Grants for investigation and research, distributed on the recommendation of the Advisory Council, are increased by £5250, and a special grant of 100,000 francs (£4000) is to be made to an international fund for the erection and endowment of a scientific station on the Col de la Jungfrau

The staff of the National Physical Laboratory is to be increased by nine, building research requires ten more officers, chemical research five, food investigation nine, forest products six, fuel research, including physical and chemical surveys, ten, radio research eight

University and Educational Intelligence

CAMBRIDGE —The Appointments Committee of the Faculty of Biology B have appointed Dr R Williamson to be University demonstrator in pathology

The Allen Scholarship of the value of £250 has been awarded to S Verblumsky, Donaldson Bye Fellow of Magdalene College

The Appointments Committee of the Faculty of Physics and Chemistry has made the following appointments Dr F G Mann, of Downing College, to be University lecturer in chemistry, Dr J D Cockcroft, of St John's College, to be University demonstrator in physics, Dr F B Kipping, of Trinity College, to be University demonstrator in chemistry

EDINBURGH —The University Court has received with very great regret intimation from Prof Baldwin Brown of his desire to retire from the Watson Gordon chair of fine art at the end of the current academical year Prof Baldwin Brown was appointed to this chair, as its first occupant, in June 1880, and so is now about to complete his fiftieth year as professor The only previous instance of a professor serving in this University for fifty years was that of Robert Jameson, professor of natural history from 1804 to 1854, in his case, however, his lectures were delivered by a deputy during his last year of office

The Court has accepted from Sir Edward Sharpey Schafer the books, portraits, specimens, and apparatus collected by him in the Department of Physiology Mrs Kennedy Fraser has offered and the Court has accepted a collection of 280 phonograph records of Hebridean songs, made by the Isle folk themselves The collection has been made in the course of Mrs Kennedy Fraser's research work in the Hebrides during the past twenty five years

The late Mr W A Tait, son of the late Prof P G Tait, has bequeathed £50 to the Engineering Library and £100 for apparatus in the Department of Natural Philosophy

LONDON —The following doctorates have been conferred D Sc in chemistry on Mr Bhupendranath Ghosh (University College), for a thesis entitled (1) "The Rôle of Electrokinetic Potential in Colloidal Behaviour", and (2) "Action of Alkali on Stannic Oxide Sol", D Sc in physics on Mr Leslie Hartshorn (Imperial College—Royal College of Science), for a thesis entitled 'Studies in Precision Alternating Current Measurements", D Sc in mathematics on Mr W G Bickley, for a thesis entitled 'Two Dimensional Potential Problems concerning a Single Closed Boundary", and other papers, D Sc (engineering) on Mr H S Rowell, for a thesis entitled "Suspension of Vehicles and Laminated Springs", and other papers

OXFORD —The annual report of the Curators of the Bodleian Library just published contains an account of recent improvements and additions in the Radcliffe (Science) Library, which now takes rank like the Indian Institute and Rhodes House Libraries, as a Departmental Library in connexion with the Bodleian

THE Grocers' Company is again offering scholarships, each of the value of £300 a year, plus an allowance for expenses, in furtherance of original research in sanitary science Applications upon a prescribed form must be received before the end of April by the Clerk to the Grocers' Company, Grocers' Hall, E C 2

APPLICATIONS for Beit fellowships for scientific research are invited from candidates under the age of twenty five years on the date of election The latest date for the receipt of applications is April 15 Forms of application and particulars as to the fellowships are obtainable from the Rector, Imperial College of Science and Technology, South Kensington, S W 7

THE Carnegie Trust for the Universities of Scotland endows post graduate study and research by means of a scheme designed, to quote from the report of the chairman, Lord Sands, on the administration of the Trust for the year 1928–29, "to discover and if possible to supply within the limits of the Trust Deed the demand for higher study and research throughout Scotland" For the completer fulfilment of this purpose, the trustees have resolved that in future graduate scholarships which carry an annual stipend of £175 for two years may be extended for a third year with a stipend of £200, and that the value of fellowships, tenable for a maximum period of three years, shall be £300 per annum instead of, as at present, £250 It will now be possible for a Scottish graduate to be engaged in research under the auspices of the Trust for a continuous period of six years Reports on the work of investigators by Prof Arthur Smithells (physical and chemical), Prof J T Wilson (biological and medical), Sir George Macdonald (historical, economic, and linguistic), and the Superintendent of the Royal College of Physicians, Edinburgh, afford ample evidence of the value of this work Prof Smithells notes with gratification an increasing encouragement of beneficiaries to secure the great advantage of some experience in foreign laboratories During the past year, the actual expenditure for endowment of research was £17,514, grants to universities, etc, amounted to £48,020, and assistance to students in payment of class fees to £56,453 Repayments (voluntary) by former beneficiaries (31 men and 32 women) amounted to £2606, the largest amount ever received in this way in any year, and making with similar repayments in previous years an aggregate of £25,148 from 665 beneficiaries.

Historic Natural Events

Mar 17, 1669 Blood Rain at Chatillon-sur-Seine —The history of the Paris Academy of Sciences says "There fell in various parts of the city, a sort of rain, or reddish liquid, thick, viscous, and stinking, which resembled a rain of blood The prints of great drops of it were observed on walls" It is believed that this rain was composed of stagnant muddy water, raised by a whirlwind from some pond in the neighbourhood

Mar 17, 1906 Earthquake in Formosa —This destructive earthquake, by which 1266 persons were killed and 7284 houses were totally destroyed, was chiefly remarkable for the somewhat complex distortion of the ground, along a fault at least 10 miles and possibly 30 miles in length Throughout the observed length, the north part of the fault was displaced horizontally with respect to the other 2 8 ft to the east, and in the greater part was depressed by 3 4 ft At the east end, however, the vertical movement was reversed, and the south side was depressed relatively to the other by as much as 6 ft

Mar 18, 1667 Great Cold —The winter of 1666–67 was known in Germany as "the double winter", because the rivers were frozen twice January was cold, February was snowy, but the greatest intensity of the frost occurred from Mar 18 until Mar 26, with north easterly winds The Zuider Zee was full of ice, and waggons were drawn over the rivers No one remembered such severe weather so late in the season In England the winter was not especially severe, but the spring was very cold On Mar 6, Pepys wrote "The weather, too, being become most bitter cold, the King saying to day that it was the coldest day he ever knew in England", and again on Mar 7 "This day was reckoned by all the people the coldest day that ever was remembered in England" Evelyn recorded "Great frosts, snow, and winds prodigious at the vernal equinox, indeed it had been a year of prodigies in this nation, plague, war, fire [the Great Fire of London], tempest, and comet" On April 4 he added "The cold so intense that there was hardly a leaf on a tree"

Mar 19, 1719 Great Fireball —A brilliant apparition was seen from the whole of Great Britain and Ireland, Holland, and from the nearer parts of Germany, France, and Spain Halley discussed collected observations made of this meteor or fireball in *Phil Trans*, p 978, 1719 In parts of England "within doors the Candles gave no manner of Light", indeed, "for some few Seconds of Time, in all respects it resembled perfect Day" In London the path of the fireball (timed as at 8 15 P M) lay nearly in the direction of the Pleiades and Orion's belt The moon, it may be noted, was nine days old The track deduced by Halley was from over Presteigne (height 73 miles), Cardiff, Tiverton (height 69 miles) to Brest There were two explosions, the first when the fireball was over Tiverton, when the sound of it, accompanied by an air tremor causing windows and doors to rattle, was heard over an area extending from Cornwall to London, the second and greater explosion took place at the extinction of the fireball over Brittany The diameter of the fireball is stated to have been fully $1\frac{1}{2}$ miles, and its velocity along the visible part of its track nearly 60 miles a second

Mar 20, 1784 Mirage at Malta —At 1 P M great excitement was aroused in Malta by the sudden appearance of what seemed to be a new island Sailors and fishermen hurried out to take possession of it, but it proved to be the top of Mount Etna, and later the hills and buildings of Sicily became visible The appearance of the mountain top as an island indicates that no rays from such lower parts of the land as were normally visible could reach the observer's eyes, and that the horizon was brought much closer than usual

Mar 21, 1920 Sunspots and Aurora —The date of central meridian passage of an enormous stream of sunspots, visible to the naked eye on this day as a curved streak nearly $\frac{1}{4}$ of the sun's diameter This region of the sun was active for about six months, and in the previous January contained another large stream but slightly inferior in size to that of March The length of these streams was of the order of 150,000 miles, the aggregate area of the component spots being about 2500 millions of square miles On Mar 22–23 a severe magnetic storm occurred, the ranges in declination at Greenwich and Stonyhurst were 86′ and 160′ respectively, whilst the ranges in horizontal force at both observatories exceeded 700γ The accompanying auroral display was the finest seen for many years In parts of Great Britain, objects at several yards' distance could be plainly seen at midnight, and at times even newspaper print could be read At Eskdalemuir, the 'curtain' extended to within 30° of the southern horizon

Mar 22, 1205 End of Long Winter —Although not especially severe, the winter of 1204–5 was very prolonged in north west Europe and England, the greatest cold lasting from the middle of January to Mar 22 It was followed by great mortality among animals in Europe, especially sheep and birds, and this resulted in a famine In England there was great distress, and Stow records that a "quarter of oats [was sold] for forty pence, that were wont to be sold for fourpence Also the money was so sore clipped that there was no remedy but to have it renewed"

SUPPLEMENTARY

Mar 9-10, 1891 West of England Blizzard —During the passage of a deep barometric depression eastwards along the English Channel, heavy snow fell with high winds over southern England, and especially in the south west According to Mr Bonacina's account in the *Meteorological Magazine* for 1927, in Devon and Cornwall the depth of snow averaged two feet with immense drifts Trains were not only blocked but actually buried in snow, and some of the passengers nearly died of starvation The 'Zulu Express' which left Paddington at 3 P M on Mar 9 did not reach Plymouth until 8 30 P M on Mar 13 The Devonshire lanes remained blocked until the end of March, and it is said that the snow remained on the higher parts of Dartmoor and Exmoor until June There were a number of shipwrecks, especially on the south coast of Devon and Cornwall, in which many lives were lost

Societies and Academies

LONDON

Royal Society, Mar 6 —W J Elford Structure in very permeable collodion gel films and its significance in filtration problems Optical studies have revealed two definite types of structure (i) microgel structure of microscopic order, (ii) ultragel structure of ultra microscopic order Gelation here is a process of phase transition resulting from the coagulating influence of desolvation The nature and stability of the gel is a function of the specific characters of the nitro cellulose and solvent, and the variation in free surface forces around the dispersed phase particles with differing degrees of molecular complexity of the system A complete explanation of the general behaviour of ultra filter membranes is afforded —T W Wormell

Vertical electric currents below thunderstorms and showers This paper describes observations on the discharge of electricity beneath thunderstorms and showers from a raised metal point, 12 3 metres above the ground In the course of a year, the net effect of the point is to discharge about + 0 13 coulombs into the atmosphere The majority of the clouds observed were of positive polarity, that is, mean height of positive charge in cloud was greater than mean height of negative charge In the locality in question, the effective gain of negative electric charge by the earth through the mechanisms of point discharge currents and lightning discharges is at least as large as the sum of the positive charges brought down by the fine weather current and by rain The observations are in agreement with C T R Wilson's hypothesis that downward current in fine weather regions from upper layers of atmosphere to ground is, on the average, balanced by upward current in regions of cumulo nimbus from earth through cloud to upper atmosphere —**G T Morgan** and **G R Davies** Antimony analogues of the carbazole series A description of the anti monial analogues I of the carbazole series II The following structural formulæ represent this analogy, where X is an alkyl or aryl radical

I   II

The starting point in this investigation is commerci ally available diphenyl —**R Fort** and **C N Hinshelwood** The kinetics of the oxidation of gaseous benzene The oxidation of gaseous benzene is a predominantly homogeneous reaction The rate of reaction varies according to a high power of the benzene concentra tion, and a high ratio of benzene to oxygen favours rapid oxidation It appears probable that compara tively short reaction chains are propagated, the variation in the length of which gives rise to the abnormal influence of temperature and pressure on the velocity The chains are propagated more readily when the initial oxygenated product encounters another molecule of hydrocarbon than when oxidised further by oxygen —**A Unmack, D M Murray-Rust,** and **Sir Harold Hartley** The conductivity of thio cyanates in methyl alcohol At 25° C the univalent thiocyanates obey the square root relationship $\Lambda_c = \Lambda_0 - x\sqrt{c}$, and the degree of association is slight, but increases with the atomic number of the metal The divalent thiocyanates fall into two groups those of barium, strontium, calcium, and magnesium, which show considerable association, and zinc and cadmium thiocyanates, which are weak electrolytes —**S J Wright** The elasticity of Pintsch crystals of tungsten The torsional moduli of rigidity of six wires, of which five were single crystals of tungsten of different orient ations, while the remaining one consisted of three crystals, were determined by a dynamical method The results indicated that the variations in elastic properties of tungsten crystals over the whole range of possible orientations would not exceed 1 part in 200 It is concluded that tungsten crystals are isotropic —**Ramakrishna Rao** Study of electro lytic dissociation by the Raman effect (1) The Raman line at 4566 8 A is common to nitric acid and nitrates, it is due to the NO_3 ion, and increases in intensity with increasing dilution of nitric acid The line at 4620 3 A is present only in nitric acid, and corresponds to the undissociated HNO_3 molecule It diminishes rapidly in intensity with increasing dilution, indicating dissociation of nitric acid Varia tion of the degree of dissociation is similar to that found from conductivity measurements but different in order of magnitude

Society of Public Analysts, Feb 5 —**R L Andrew** The determination of minute amounts of iodine in soils and waters A modification of Fellenborg's method has been devised and 60 70 per cent of iodine added to a soil can be recovered The results obtained by colorimetric methods are more trust worthy than those obtained by titration Soils from the North Island of New Zealand contained from 10 to 2100 parts of iodine in 10 millions, and the drink ing waters from 0 004 to 0 120 part per 10 millions —**D W Kent-Jones** and **A J Amos** Preliminary studies in the bacteriology of wheat and flour A satisfactory procedure for enumerating bacteria in wheat and flour has been devised Freshly and normally milled patent flour contains less than 20,000 blood heat bacteria, straight run flour less than 50,000, and lower grade flour up to 300,000 per gm The cool organism content of any grade is nearly always greater than that for blood heat organisms Storage decreases the number of both forms Organisms of the *B mesentericus* group are almost universally present in flour and bread —**H J S Sand** The separation of metals by internal elec trolysis' The metal to be determined is deposited on a platinum cathode, the essential feature of the method being that no electric current is introduced from outside, but, instead, an anode of the baser metal is employed, which is placed in contact with a solution of one of its salts in a compartment separated by a parchment membrane from the solution to be ex amined —**Ella M Collin** The rapid determination of bismuth and copper in lead bullion by internal electrolysis The method has been used to separate small quantities of bismuth and copper from large amounts of lead, the less basic metals being displaced from solution by means of lead, without any external E M F —**G Winthrop Leeper** Notes on the thio cyanate method of determining iron Influence of different classes of phosphates Orthophosphates do not interfere with the thiocyanate reaction provided that the ratio of phosphoric anhydride to iron does not exceed 100 0 02 mgm When extracting the ashed material with acid sufficient time must be allowed for any pyrophosphate formed to be recon verted into orthophosphate Both pyrophosphates and metaphosphates rapidly destroy the colour of ferric thiocyanate

Physical Society, Feb 14 – **W E Summerhays** The diffusion constant of water vapour Water vapour was allowed to diffuse down a vertical tube about 2 in in diameter, a steady concentration gradient being maintained from approximate satura tion at the top to approximate dryness at the bottom The gradient was measured with two katharometers at a definite distance apart and the mass of vapour passing in an observed time was weighed The result is 0 281 cm ^{2}/sec at mean temperature 16 1° C —**M C Johnson** A method of calculating the numerical equation of state for helium below 6° abs, and of estimating the relative importance of gas degeneracy and interatomic forces Gas 'degeneracy' (the effect of non Maxwellian distribution of molecular velocities) is distinguished from gas 'imperfection' (the effect of intermolecular forces) A thermodynamic method is used to calculate the sum of degeneracy and im perfection at 4° and 5° abs for helium —**F D Smith** The magnetostriction constant for alternating mag netic fields A magnetostriction constant K for the Joule effect is defined by the equation $p = KH$ where p is the alternating mechanical stress produced by a

small alternating magnetic field H superposed on a steady magnetic field H_0. It is shown that the alternating intensity of magnetisation I produced by an alternating strain $\delta l/l$ is given by the equation $I = K^{\delta l/l}$, K being the same constant in both equations. These equations are used to calculate the motional impedance of a laminated ring toroidally wound and vibrating in its fundamental radial mode.

DUBLIN

Royal Dublin Society, Jan. 28.—**Henry H. Dixon** and **T. A. Bennet-Clark**: (1) Responses of plant tissues to electric currents. Previous experiments on plant tissues revealed an S shaped relation between response and voltage. This result might be interpreted as due to the response of cells of modal size in the conducting tissue to a certain voltage, each cell responding on the 'all or none' principle; or it might be that the responses of the individual cells vary in magnitude, and that a modal response is given by these cells to a certain voltage. In the present experiments, the staminal hairs of *Tradescantia* consisting of a single filament of cells were used. The same S shaped relation was found. Hence it is evident that the component cells gave responses of different magnitudes according to the voltages applied, and that the 'all or none' principle taking the cells as units is not effective. This result was confirmed on other filiform tissues.—(2) Electrical properties of emulsions. Emulsions of water and olive oil containing both sodium and calcium soaps were prepared so that exceedingly slight increase in the [Na]/[Ca] ratio caused the emulsions to change from the water in oil state to the oil in water state. This change occurred when a sufficient potential difference was applied across the emulsion. The effect was detected most readily by noticing the change in resistance of the emulsions. These were of the order of 10 megohms before the stimulus, and between 1 megohm and 100,000 ohms after. Living protoplasts and water in oil emulsions are apparently the only systems of which the electrical conductivity changes in this manner as a result of the application of an electrical stimulus.—**C. O'Sullivan** and **J. Reilly**: Studies in peat (4). Low temperature carbonisation under various conditions.—**H. A. Cummins**: Experiments on the establishment of rice grass (*Spartina Townsendii*) in the estuary of the Lee.

PARIS

Academy of Sciences, Feb. 3.—**Marcel Brelot**: The equation $\Delta u = cu$, where $c > 0$ admits singular points, and a corresponding Fredholm equation with singular nucleus.—**S. Soboleff**: The analytical solutions of partial differential equations with two independent variables.—**J. S. Lappo-Danilevski**: Observations on the note "Analytical functions of a single variable substitution".—**T. Takéuchi**: The Brownian movement in a field of thermal radiation.—**E. Darmois** and **J. Martin**: The influence of alkaline molybdates on the rotatory power of glucose. Studies of the rotation of glucose solutions in solutions containing sodium hydroxide and molybdenum trioxide as a function of the time. The results suggest the formation of a compound $NaMoO_4,2C_6H_{12}O_6$.—**E. Sevin**: The emission of spectral lines in an electric field.—**R. Deaglio**: The action of light on thermionic phenomena. When the thermionic current is far from saturation, the increase of the thermoelectronic current produced by light on the filament is almost completely a true photoelectric effect.—**Er. Toporescu**: The potentials of metals in pure liquids. From the study of the potential differences shown by a platinum-zinc couple in various alcohols, it was found that there is no parallelism between the potential differences and the dielectric constants of the liquids.—**S. Schlivitch**: The photochemical transformations of photovoltaic batteries.—**F. Bourion** and **E. Rouyer**: Boiling point study of the molecular equilibria of resorcinol in solutions of barium chloride.—**Ballay**: Electrolytic deposits on aluminium and its alloys. For the preliminary treatment of the aluminium or alloy a hot slightly acid solution of ferric chloride is proposed. After this treatment, nickel can be deposited electrolytically as a strongly adherent film.—**R. Cornubert**: The constitution of the so called tetrahydropyronic compounds.—**Max** and **Michel Polonovski**: The passage of a tertiary aminoxide into a dialkylhydroxylamine. N-oxynornarceine.—**Pierre Viennot**: The geology of the Rhune massif (Basses-Pyrénées).—**Cazalas**: The evolution of the vacuome of *Chara* in its relations with the movements of the cytoplasm.—**Mlle. Gabrielle Bonne** and **S. Buchet**: A curious case of floral proliferation in *Rosa alpina*.—**G. Dinulescu**: The presence in France of *Gastrophilus inermis*. The larvæ, obtained from horses suffering from the disease caused by this parasite, were transferred to a suitable medium and growth to the final stage completed outside the animal.—**L. Mercier**: The variation of certain pieces of the male genital sheath of *Pollenia rudis*; the importance of this variation for the idea of species in the higher Myodaria.—**Raymond Hovasse**: A new mode of symbiosis in cochineal insects.—**E. Roubaud**: Evolutionary suspension and obligatory larval hibernation, caused by heat, in the common mosquito, *Culex pipiens*. True diapauses and pseudo diapauses in insects.—**J. Lefèvre** and **A. Auguet**: The influence of the hygrometric state of the air on metabolism. Hypotonus in a moist warm medium. Making use of the calorimetric chamber described in an earlier communication, experiments with sheep proved that for relative humidities less than 85 per cent, the evaporation of the body is not disturbed, but when the humidity exceeds 90 per cent the loss of heat by evaporation falls rapidly and the metabolism is diminished. These results are discussed from the theoretical, hygienic, and practical points of view.—**Pierre Girard** and **J. Parrod**: The formation of hydroxymethyl 4 imidazol, at low temperatures, starting with fructose in a solution of ammoniacal cupric hydroxide. The slow oxidation of lævulose, by shaking with oxygen in ammoniacal copper solution, gave a base, identified through its picrate as hydroxymethyl 4 imidazol.—**A. Paillot**: The cellular and humoral reactions of antimicrobial immunity in the phenomena of symbiosis in *Macrosiphum Jaceæ*.—**Y. Manouélian**: Hereditary syphilis and evolutionary forms of the treponeme.—**J. Alquier, Mlle. L. Asselin, Mme. M. Kogane** and **Mlle. G. Silvestre de Sacy**: The variations of the mineral composition of the bone tissue in the normal rat, rachitic rat, and the rat cured of experimental rickets. The cure of rickets, controlled both clinically and radiologically, does not necessarily imply that the mineral composition of the bone has returned to the normal.

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Sir Ernest Rutherford Atomic Nuclei and their Structure (2).

ROYAL IRISH ACADEMY (Dublin).

MONDAY, MARCH 17

ROYAL SOCIETY, EDINBURGH, at 4 30.—F Walker The Doleritic Isles of the North Minch —W J McCallien and R. B Anderson The Carboniferous Sediments of Kintyre —W J McCallien A Contribution to the Geology of North Eastern Antrim being an Introduction to the Correlation of the Dalradian Rocks of Scotland and Ireland —Lt.-Col L M Davies The Genus *Dictyoconus* and its Allies A Review of the Group, together with a Description of Three New Species from the Lower Eocene Beds of Northern Baluchistan —D F Martyn On a New Method of Measurement of Minute Alternating Currents

VICTORIA INSTITUTE (at Central Buildings Westminster), at 4 30 —Rev C Gardner How far do the Apologetics of Bacon, Butler and Paley hold good for Present Use?

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —C E Shattock Demonstration of Diverticula.

KING S COLLEGE ENGINEERING SOCIETY, at 5 15.—W H. Dormer Haulage in Coal Mines

BEDSON CLUB (at Armstrong College, Newcastle-upon Tyne), at 6.30 —Dr E K Rideal Some New Properties of Unimolecular Films (Bedson Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —A. F Harmer and others Discussion on High Tension Substation Control Gear

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section, London), at 7 —W Taylor Science in Works Management (Lecture).

INSTITUTION OF AUTOMOBILE ENGINEERS (Glasgow Centre) (at Royal Technical College, Glasgow), at 7.30.—H. R. Ricardo: Combustion in Diesel Engines.
BRADFORD TEXTILE SOCIETY (at Midland Hotel, Bradford), at 7.30.—J. H. C. Hodgson: International Co-operation in the Textile Trade.
HUDDERSFIELD TEXTILE SOCIETY (at Huddersfield Technical College), at 7.30.—G. R. Carter: The Peculiar Economics of the Textile Industry.
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.30.
ROYAL AERONAUTICAL SOCIETY (Halton Branch).—Metal Construction of Aircraft.

TUESDAY, MARCH 18.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. H. Hunter: The Significance to Clinical Medicine of Studies in Calcium and Phosphorus Metabolism (Goulstonian Lecture).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. C. Singer: The Passage from Mediæval to Modern Science (2): The Science of the Renaissance.
MINERALOGICAL SOCIETY, at 5.30.—Prof. W. L. Bragg: The Structure of Silicates (Lecture).
ROYAL SOCIETY OF MEDICINE, at 5.30.—General Meeting.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Col. A. E. Hamerton: Report on the Deaths occurring in the Society's Gardens during the Year 1929.—Dr. H. F. Barnes: On some Factors Governing the Emergence of Gall Midges (Cecidomyidæ: Diptera).—G. Dollman: On Mammals obtained by Mr. Shaw Mayer in New Guinea and presented to the British Museum by Mr. J. Spedan Lewis.—G. E. Hutchinson: Report on *Notonectidæ*, *Pleidæ* and *Corixidæ* (Hemiptera Heteroptera) collected during Mr. Omer Cooper's Expedition to Abyssinia.—A. Stanley Hirst: On some Australian Acari (Trombidiidæ, Anystidæ, and Gamasidæ).
INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—D. J. Watkins: Electric Locomotives.
LONDON NATURAL HISTORY SOCIETY (at Winchester House, E.C.), at 6.30.—Dr. A. Thomson: The Pecten of the Bird's Eye.
TELEVISION SOCIETY (Annual General Meeting) (at University College), at 6.30.—Sir Ambrose Fleming: The Relation of Governments to Invention (Presidential Address).
INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers' Club, Manchester), at 7.—H. W. Taylor: Voltage Control of Large Alternators.
ILLUMINATING ENGINEERING SOCIETY, at 7.—The Lighting of a Large Liner.
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Section—Manchester and District Branch) (at Milton Hall, Manchester), at 7.
INSTITUTE OF METALS (Birmingham Local Section) (at Chamber of Commerce, Birmingham), at 7.—W. R. Barclay: Nickel Chromium Alloys.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Kinematograph Group—Annual General Meeting), at 7.—A. Kossowsky: Modern Methods of Sound Reproduction in Kinematography.
INSTITUTION OF AUTOMOBILE ENGINEERS (Wolverhampton Centre) (at Engineering and Scientific Club, Wolverhampton), at 7.30.—Capt. J. S. Irving: Problems Encountered in the Design of the *Golden Arrow*.
INSTITUTE OF METALS (North East Coast Local Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Annual General Meeting.
INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry—Edinburgh and East of Scotland Section) (at 36 York Place, Edinburgh), at 8.—Prof. S. A. Smith: Poisoning and Disease in Industry.
ROYAL SOCIETY OF MEDICINE (Pathology Section), at 8.—Annual General Meeting.

WEDNESDAY, MARCH 19.

SOCIETY OF GLASS TECHNOLOGY (at Talbot Hotel, Stourbridge), at 2.—G. V. Evers: Notes on the Manufacture of Refractory Materials in America.—Dr. J. H. Partridge and H. C. Biggs: Glasshouse Refractories. A Study of Corrosion Resisting Properties.—F. C. Gough: Some Practical Results with Sillimanite for Glasshouse Refractories.
ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5.15.
OVERHEAD LINES ASSOCIATION (at Institution of Electrical Engineers), at 5.30.—Dr. Eckstrom: Comparative Costs of Overhead and Underground Transmission Lines.
INSTITUTION OF AUTOMOBILE ENGINEERS (Leeds Centre) (at Metropole Hotel, Leeds), at 7.15.—W. J. Morgan: Organisation of Public Service Motor Vehicle Repair and Maintenance Systems.
INSTITUTION OF LOCOMOTIVE ENGINEERS (Birmingham Centre) (at Chamber of Commerce, Birmingham), at 7.15.—W. Kay: Mineral Oils and Lubrication.
SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (at University College, Nottingham), at 7.30.—Dr. H. Levinstein: Some Derivatives of Cellulose and their Industrial Application (Lecture).
ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Dr. H. Lapworth: Meteorology and Water Supply (G. J. Symons Memorial Lecture).
ROYAL SOCIETY OF ARTS, at 8.—Mrs. Arundell Esdaile: The Portrait in Later Monumental Sculpture.
FOLK-LORE SOCIETY (at University College), at 8.—Mrs. R. Aitken: Saint Dominic of the Road and the Cock that crowed in the Dish.
ST. PAUL'S ECCLESIOLOGICAL SOCIETY (Annual Meeting) (at Royal Institute of British Architects), at 8.—At 8.30.—H. W. Fincham: Ely.
ROYAL MICROSCOPICAL SOCIETY, at 8.—J. E. Barnard: Resolution and Visibility in Medical Microscopy (postponed Presidential Address).
ROYAL AERONAUTICAL SOCIETY (Yeovil Branch).—Major C. J. Stewart: High Altitude Equipment for Aircraft.
ROYAL AERONAUTICAL SOCIETY (Coventry Branch).—Wing-Comdr. T. R. Cave-Browne-Cave: The New Airships Machinery.
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre).

THURSDAY, MARCH 20.

ROYAL SOCIETY, at 4.30.—Discussion on Catalytic Reactions at High Pressures, to be opened by Prof. G. T. Morgan, followed probably by M. P. Applebey, Prof. W. A. Bone, Prof. H. B. Dixon, Prof. F. G. Donnan, Dr. F. A. Freeth, S. J. Green, C. N. Hinshelwood, E. J. Lush, Col. Pollitt, Dr. E. K. Rideal, Dr. R. E. Slade, and Prof. R. V. Wheeler.
LINNEAN SOCIETY, at 5.—Dr. C. Tate Regan: A Ceratioid Fish (*Caulophryne polynema*, sp. n.), Female with Male, from off Madeira.—Lt.-Col. J. Stephenson: An Oligochæte Worm Parasitic in Frogs of the Genus *Phrynomerus*.—Capt. F. Kingdon Ward: Mishmi Hills and Assam.
ROYAL SOCIETY OF MEDICINE (Dermatology and Medicine Sections), at 5.—Discussion on The Therapeutic Value of Gold Compounds, Sanocrysin, etc.
KING'S COLLEGE ENGINEERING SOCIETY, at 5.15.—S. B. Thomas: Motoring: Its Progress in the Last Thirty Years.
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—J. B. S. Haldane: Some Problems of Genetics.
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—Dr. B. Leggett: The Medical and Surgical Applications of Electricity.
SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (Annual Meeting) (at Chamber of Commerce, Birmingham), at 6.30.—At 7.—Dr. W. R. Ormandy: A Wood Distillation Factory in Jugo Slavia.
INSTITUTION OF ELECTRICAL ENGINEERS (Hampshire Sub-Centre) (at University College, Southampton), at 7.
INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.—W. J. Girvan: The Practical Application of the Principles underlying the Equitable and Profitable Sale of Electrical Energy.

Progressive Physics

THE conception of segregation and integration put forward by Herbert Spencer in his "First Principles" seems to be illustrated by changes in the character of the correspondence columns of NATURE in recent years During the War, and even before, few communications to these columns were published from scientific workers outside Great Britain, the process of segregation tended to collect them around separate geographical centres Since then, however, the international outlook of science has begun to reassert itself, and investigators everywhere desire to make their methods or results as widely known as possible Early publication serves a useful purpose, not only as a preliminary announcement of work to be described more fully later in a special journal or before a scientific society, but may also save other investigators from devoting time to a piece of research work which is being carried on elsewhere

This function of the correspondence columns of NATURE has become increasingly important since what Prof Smithells has called 'electronomy' became a branch of physical science, and stimulated active work in a wide and fertile field of mathematical and experimental inquiry At the present time, more attention is devoted to explorations of this field than to any other scientific region, and this activity is reflected in our correspondence columns as it is in the *Proceedings of the Royal Society* NATURE is, however, an international journal of science, and communications for publication as 'Letters to the Editor' come from many countries

An accumulation of such correspondence is relieved to a slight extent this week by the publication of a Supplement containing a number of letters on atomic physics and related subjects The variety and intricacy of the subjects dealt with in these letters illustrate most forcibly the difficulty inevitably encountered by any physicist who attempts to keep himself familiar with even the barest outlines of work being carried on outside his own special branches, and *pari passu*, the problem in selection of material which confronts teachers of the more advanced portions of the subject

The value of the critical accounts of current research which appear from time to time in the *Physikalische Zeitschrift*, the new *Physical Review Supplement*, and other journals, and in the small monographs now being published in Great Britain as well as in Germany and France, cannot be overstated, whilst Prof Sommerfeld's 'Wellen mechanischer Erganzungsband", probably in as wide use as his classical "Atombau and Spektrallinien", offers the wave mechanics as a useful

tool and mode of expression of results to those whose interests are primarily experimental At the same time, the theoretical equipment which is essential for a full appreciation of the implications of the new mechanics is so heavy that the active co-operation of a trained mathematician is as necessary in much laboratory work as the services of a glass-blower and mechanic

There is at least one important branch which does not happen to be represented in the supplement, namely, that concerned with the line spectra of atoms Hund's theory of spectra, which permits of the prediction of the exact types of spectral terms that will result from any configuration of the electrons of an atom, has already led to such great advances in the analysis of complicated spectra that the analysis of *all* line spectra now appears to be only a question of time There are still notable gaps, particularly in connexion with extreme ultra violet spectra and the spectra of the rare earths, but these no longer offer the seemingly insuperable barriers they once presented It must be remembered, too, that Hund's theory correlates the terms of spectra with the discrete energy states of the atoms in far more detail than in the parent theories of Bohr and Sommerfeld, so that, for example, H N Russell's analysis of the arc spectrum of titanium is in effect a statement of the individual energies of hundreds of known configurations of neutral titanium atoms, and gives these energies with the high precision of spectroscopy

This subject still offers a wide field for experimental research, as does the problem of the intensities of lines, of particular importance in astrophysics in view of the wealth of material offered by stellar spectra The origin of the lines of the coronal spectrum of the sun has still, however, to be established, and the 'forbidden' lines of oxygen, nitrogen, and iron found in some stars and nebulæ have still to be produced in the laboratory

Band spectra continue to attract much attention, and here again Prof Hund has been largely instrumental in placing the theory of molecules on a sound basis The fortunate fact that Raman spectra can be obtained without extraordinary difficulty is also leading to the accumulation of much valuable information about the properties of molecules—there are no less than five communications on this subject in our Supplement, and it is perhaps not looking too far ahead to envisage a time when an enumeration of the infra red frequencies of a new compound will be regarded as necessary to its description as melting-point and crystal structure

The extent to which experimental research has been fostered during the last decade by the large commercial laboratories, in particular by those interested in the production of lamps and wireless apparatus, has still perhaps to be appreciated fully Quite apart from the work done directly by these bodies, which includes such important contributions to pure science as Davisson and Germer's work on the diffraction of electron waves and Langmuir's investigations of the properties of highly ionised gases, a high standard for manipulation has been created, the necessity for which arises from such facts as the making or marring of the electron-emitting properties of a filament by a layer of impurity on the surface one atom thick The widespread use of diffusion pumps, the less general, but highly desirable use of induction furnaces for degassing metals *in vacuo*, and the introduction of new types of glass for containing vessels have come largely from their example and pioneer work

In one respect, however, the activities of the commercial laboratories and other non-academic establishments are a little disquieting As Prof Andrade has pointed out, twenty-five or thirty years ago the young man who wanted to devote his life to experiment turned automatically to the universities, now, if he wants to earn a living, he turns, almost automatically, away from them (*Journal of Scientific Instruments*, February 1930, p 49) It is highly probable that the universities will nevertheless continue to be the home of theoretical physics, and it may be questioned if this partial divorce of the two main branches of the subject will be for the ultimate good of either

---

Problems of Plant Physiology

Growth and Tropic Movements of Plants By Sir Jagadis Chunder Bose Pp xxix + 447 (London, New York and Toronto Longmans, Green and Co, Ltd, 1929) 21*s* net

ON examining the prolific publications of Sir Jagadis Chunder Bose, concerning various plant physiological phenomena, one is inevitably impressed by the unique style which he adopts in attacking the various problems with which he has dealt His methods are often stupendous in their departure from orthodoxy (for which, maybe, he is to be congratulated), in experimental accuracy, and in the forethought for possible experimental error His results, too, have often astounded many of his contemporary workers, but their value, unfortunately, is too often uncertain, through his being rather precipitate in drawing his conclusions

Such a generalised opinion of his works is scarcely changed by this publication, "Growth and Tropic Movements of Plants", his latest work Yet, whatever one may feel about the value of the bulk of this author's work from a purely physiological point of view, one must admit its value in other ways There probably are very few plant physio-

logists who have attacked so many controversial problems in such an original manner This, at any rate, stimulates thought and criticism in others, which is all to the common good Such may be said of nearly all Bose's work, and especially of his well-known exploits into the mysteries of plant responses and the ascent of sap in plants

In this new series of investigations, Bose has certainly maintained his reputation as an original worker along unusual lines His methods are exclusively his own, and in an admirable fashion does he go on, not from where a previous worker left off, but in a manner peculiar to himself In this work on growth and tropisms, the experimental method is, in general, brilliant if not for its accuracy, then for its originality But these phenomena, like all others, demand an ultimate exposition of the truth This can never be cloaked, as an ideal, however enthusiastic one might become over a certain theory One feels, therefore, to do this, we should strive for it in as simple a way as possible Simplicity, so far as it can be indulged, is always the more desirable, so long as it maintains a practicably natural state of affairs, and this is possibly where Bose still remains at fault, for his experimental methods are usually far too complex in construction

In striving to give weight to his convictions, Bose—broad-minded as he is in his outlook on science (the science of the universe, as he calls it elsewhere)—misses the mark very badly in his unfortunate exclusiveness where the work of others is concerned Correlation of results of different workers is not only helpful to the student, but also is it essential, if such results are to carry any degree of conviction This exclusive attitude of Bose, this failure to emphasise contrasts and comparisons with the work of others, has been exemplified so often as sometimes to prove exasperating, and such aloofness is demonstrated here again

The majority of the methods involved in this new series of investigations are similar to the previous ones adopted by the author, in that the plant is made to record its own autograph Yet one or two are worthy of special note

Several new methods are described for the measurement of growth in plants The author's criticism against the orthodox type of instrument, the auxanometer, is that an undesirable length of time is necessary before any appreciable result can be obtained The auxanometer, in any case, is of little use, except for demonstration purposes, and such criticism is so clear as to be unnecessary However, the new apparatus is undoubtedly much more desirable than the auxanometer

Bose's high magnification creseograph is a splendid piece of apparatus which obviates many of the usual errors In it is used the optical lever, which the author introduced into experimental physiology several years ago Much experimental error, such as tension due to levers, stretching of connexions and friction at the fulcrum, has been ingeniously eliminated

This creseograph is claimed to be highly sensitive, measuring a very small increase in growth, over an exceptionally small period of time To quote an actual statement, Bose claims that this apparatus permits the record of growth elongation of 0 00005 mm and a difference can be seen over an interval of 0·05 second This is indeed sensitive as compared with methods which have been previously at the disposal of the plant physiologist

In his studies of growth phenomena, Bose still maintains his conception of rhythmic pulsations in life processes This is exemplified in his statement that growth is a pulsatory movement, being the resultant difference in each pulsation between elongation and recovery This suggestion is a very plausible one, no doubt, but the experimental evidence obtained by the investigator appears to be considerably lacking in conviction

Two other methods of measuring growth are described in the book One is termed the "Method of Falling Weight", and the other the "Method of the Inclined Plane" Neither, however, seems to be so sensitive as the optical lever creseograph In all three cases, the author takes change in linear dimension as an expression of growth This, of course, cannot be accepted without reservation, yet, in spite of this and other drawbacks, the methods (and especially the first) might be used with advantage in any plant physiology laboratory, if only for demonstration purposes

Many studies on the effect of conditioning factors of growth are described These, however, have produced few observations of paramount importance, and, on the whole, the results are rather disappointing In these investigations, too, Bose betrays a definite determination to introduce new methods, to the exclusion of other already established ones, which may be better This is clearly emphasised in his experiments on the effect of temperature, although his own method is perhaps better, for obtaining gradual changes in temperature Otherwise, a gas or electric thermostat would perhaps meet the case much more efficiently

In all this work on growth, surprisingly little has been brought forward of any value from the point of view of newness or possible revolution of ideas

that, we would naturally look for, since our knowledge of growth phenomena is so deplorably inadequate at present The first section of the book, therefore, apart from one or two methods which are decidedly well worthy of note, is disappointing

In the second part of his book, Bose has attacked the problems involved in plant tropisms Here his investigations begin with the assumption that he is out to prove that the average physiologist is quite wrong in his conception of the various mechanisms involved in tropistic curvatures Despite the many theories put forward, the average thinker is quite prepared to admit that we know practically nothing of this section on plant life processes Bose's reference to the generalisation that shoots are positively phototropic and roots are negatively phototropic, as being "hasty", is quite unnecessary and ill founded, since this generalisation has been rejected for some time now

Bose's methods of attacking these problems are very similar to the previous ones, and again, some might well be applied to demonstration experiments, although the author emphasises again their extreme sensitiveness No new facts have been exposed, except perhaps that in all probability (although Bose states it dogmatically) the latent period may be much shorter than has been hitherto supposed This is interesting and leads one to suggest that possibly, when a still more sensitive recorder has been devised, it may be established that no appreciably latent period really exists

In his investigations on geotropism, carried on along similar lines, the author states that it is unnecessary to assume that geotropic reaction is really different in the root from that in the shoot Although many theories, concerning either one or the other or both, have been put forward by various workers, nothing has been genuinely accepted, and this assumption certainly has not His use of the term 'stimulus' and so forth involves a definite meaning for them, just as definite, so he states, as such terms in animal physiology This is only natural, of course, in view of his conception of a plant nervous system, but even now, in spite of his observations, it seems doubtful whether plant physiologists are justified in accepting these terms

Concerning the geoperceptive region, Bose makes some observations which, reactionary though they may be, might prove of considerable interest By means of an electric probe (which we have met before in this author's works), he has attempted to show (and has himself concluded) that such a region exists as a cylindrical layer, some distance below the surface of the organ This layer, one assumes from his statements, is not absolute, since it apparently merges insensibly, with declining excitability, from a maximum to a minimum nearer the surface and a minimum nearer the centre Such an observation may prove of value, but one cannot help suspecting that the methods used and the results so far obtained make the whole conception very questionable at the moment

All irritabilities, according to Bose, should not be considered as separate phenomena, but rather as variants of a common one This observation only voices the suspicions of many plant physiologists It therefore is of little value, and especially since the experimental evidence brought out is insufficient to warrant this assumption, although it certainly does not tend in any other direction

The evidence, on the whole, in the latter half of the book is meagre and lacking in conviction Much has been done which is of great interest from an experimental point of view, but little new is there to evince any theoretical considerations In fact, one might almost say that Bose could, with just as much confidence, have postulated his theories of tropisms from the few facts that have already been established by previous authors, with simpler methods

The whole book may be described as a practical note book—one written by a student with endless originality, perseverance, conception of method, and amazingly delicate technique, but also with a tendency to misconstrue results and form precipitate conclusions Nothing really new has been added to our very scanty store of knowledge of these subjects—a little more detail perhaps—and much has been done which one feels might just as well have been left undone, at any rate, for the time being We really know so little about natural phenomena and natural conditions, that to examine the effect of unnatural or artificial ones, as Bose all too frequently has done here, seems almost sacrilege, at the moment

One might say that, instead of being content with a toy of simple proportions, Sir Jagadis has assembled one of more complicated parts and enormous dimensions Thus, with enthusiasm has he spent much time with his ingenious contrivance and made it do all manner of wonderful things (perhaps with more exactitude than the simpler one, and, if so, this is desirable), but it has done nothing new, and, in such cases, there is always the risk of missing the wood for the trees, or, worse still, finding the wrong wood Much more desirable would it be to get a greater mass of trustworthy facts and, coupling them with those obtained by

other workers, make more possible deductions, rather than to set out to impress an idea at all costs, which, after all, may be wrong

Until this is done (and one feels that we have *not* been helped to any appreciable extent by this latest work), we must perforce remain in the morass of scientific hypothesis, which is decidedly unsound where tropisms are concerned, until such time as we obtain the evidence necessary to our attaining a more substantial conception of the actual truth

L J F BRIMBLE

Science in the Fifteenth Century.

Science and Thought in the Fifteenth Century, Studies in the History of Medicine and Surgery, Natural and Mathematical Science, Philosophy and Politics By Lynn Thorndike Pp xiv + 387 + 10 plates (New York Columbia University Press, London Oxford University Press, 1929) 24*s* net

IT is most satisfactory to be able to record that the last few years have been marked by an ever increasing output of literature dealing with the early history of the natural sciences, and the excellent advice of the Hebrew poet,

"Let us now praise famous men",

has been taken by many, who have thereby followed the good example of NATURE, which for several years past has made references from time to time to the achievements of bygone scientific worthies In spite of absence of manuscripts and other first hand documents in the United States, the same ends are being pursued by our friends across the water, and by none with greater enthusiasm than by Prof Lynn Thorndike of Columbia University His most recent book comprises a series of studies chosen to illustrate the thought and science of the fifteenth century, a period which is less well known than the earlier, and perhaps more fruitful, period of Roger Bacon, but which is also well worthy of investigation

To place the subject in its proper light and atmosphere, the main characteristics of fourteenth century science are outlined in a useful introductory chapter, which is calculated to astonish even those mechanical creatures of habit who, having "stopped thinking and reading twenty years ago", repeat "old slurs and disparaging generalisations at the expense of the middle ages" Our author quotes many examples of the high culture and advanced thinking of scholars of the twelfth, thirteenth, and fourteenth centuries, such as Occam, Buridon, Albert of Saxony, and also Nicolas Oresme, whose ideas concerning physics and astronomy were remarkable By 1326, Richard of Wallingford, father of trigonometry, had brought measuring instruments and clocks to a marvellous state of perfection Gunpowder, the blast furnace, the mariner's compass, and many other inventions, were all available for useful purposes even so elaborate a surgical operation as rhinoplasty had been successfully accomplished

The status of medical practitioners in the fifteenth century is illustrated by early Italian disputations as to the relative importance of medicine and law, in which it is argued that the lawyers have attained to a higher social position than the doctors, because they do not soil themselves by plunging their hands into viscera, and so on Is this, perhaps, the reason why the Royal Society includes so few surgeons among its fellows even at the present day? But it may be that the science of medicine is still, as John of Arezzo suggested, "under the rule of Mars and Scorpion invidious, malevolent, plotting against and hating all others" Then appropriately follow chapters dealing with the surgery of Leonard of Bertipaglia, an anonymous "Practica Cirurgie" assigned to John Braccia of Milan, or to Peter of Tossignano who used to prescribe caustic water, and lastly, an autopsy by Bernard Tornius, of which both the original text and a translation are printed Among minor medical writings, one by John of Arezzo on poisonous mushrooms, their appearance, black, livid, or green when cut open, their being rendered harmless when cooked with wild pears, and the symptoms of poisoning, and its cure by vomiting, have a perennial interest

In dealing with Nicholas of Cusa, Prof Thorndike strikes a more controversial note, and points out that, at least so far as the astronomical system with which the name of Cusa is associated is concerned, it is probable that exaggerated praise has been meted out to him For, so far from being an important precursor of Copernicus, Cusa scarcely carried his system beyond that of Ptolemy All he appears to have said is that the earth has a movement, and its position varies a little in consequence The work of Cusa's protégé, George von Peurbach, the Virgilian scholar and inventor of the geometer's quadrate, is next discussed He is remembered as the translator of six books of the Almagest, but unfortunately his version, having been made *breviorem lucidioremque* than the original Greek, is a poor substitute for it His reputation, like that of Regiomontanus, has "received rather undue emphasis from modern German historical scholarship, whereas until recent years the English, French, Italian, and Spanish

mathematicians of the fourteenth and fifteenth centuries have been less studied and written about"

The French arithmetic of Jehan Adam composed in 1475 concludes this section of the book The remainder deals with treatises on politics, moral philosophy, and other matters, but many readers will take pleasure in being introduced to the " De Constitutione mundi ", by John Michael Albert of Carrara, the probable sources of whose information are carefully traced by the author

We owe a debt of gratitude to Prof Thorndike and to the Dunning Fund for this volume of miscellaneous studies now presented to us

Greenland

Greenland Published by the Commission for the Direction of the Geological and Geographical Investigations in Greenland Editors Prof M Vahl, Vice Admiral G C Amdrup, Dr L Bobé, Prof Ad S Jensen (Published at the Expense of the Carlsberg Fund) Vol 2 *The Past and Present Population of Greenland* Pp iv + 415 (Copenhagen C A Reitzel, London Oxford University Press, 1928) 35s net

THE first volume of " Greenland " was reviewed in NATURE of Mar 23, 1929 This, the second of the three volumes planned, deals exclusively with the past and present inhabitants Of the six articles, three are concerned with Eskimo ethnology and archæology, and three with the now extinct tenth century colonisation by Norsemen

Dr Birket Smith provides a full and interesting account of the present day Greenlanders, their distribution, mode of life, and material culture A contrast is made between the high-arctic type at Etah (Sir John Ross's Arctic Highlanders) and the subarctic kayak-using people farther south The former can still be named Eskimo, the latter are Greenlanders, half Eskimo, half European They appear to have none of the disadvantages so often implied by the term ' half breed ', but on the other hand, with usages and habits modified by Danish influence, it can even be claimed that Greenlanders are in many ways superior to unmixed Eskimo stock Their number at the present time is about 14,000, compared with 6000 at the beginning of last century Dr Birket Smith's description is the only full and accurate account of these people written since the publication of Dr Rink's " Danish Greenland " in 1877

Shorter articles deal with intellectual culture, and with Eskimo archæology The latter, though brief, is fairly exhaustive, little excavation having as yet been undertaken The nature of the older (Thule) culture is explained Eskimo origins and the lines of immigration are discussed, from this it appears that the balance of evidence now is in favour of the view that north east Greenland was peopled by way of the north, and that the track of the immigrants lay so far north as lat 83° N

The first of the articles on the Norse settlements is a general account by Finnur Jonsson based on historical records This is followed by a description of the farm sites by Daniel Brunn, in this article reference is made particularly to the economic conditions considered likely at the time of the occupation Finally, Dr Norlund summarises the finds made at the Herjolfsnes burial ground in 1921, when well preserved clothing of fourteenth and fifteenth century type was found in ground now permanently frozen Dr Norlund concludes that the colony died out as a result of the consequences of unsatisfactory diet, and that there was a complete absence of any intermingling with Eskimo The view that there had been a setting in of colder conditions is apparently not so confidently held The three articles on the Norse settlements are brief accounts of a subject on which lately a good deal has been written they show that Danish writers at any rate have refrained from making the history of the old colonies in any way fictitious or unduly sensational

Both Eskimo and Norse sections of the book constitute most admirable accounts of the past history of Greenland and of the living conditions found there to day This book is definitely the authoritative work on Greenland and Greenlanders Apart from its being indispensable, it is exceedingly well written and well produced

J M WORDIE

Our Bookshelf

Die Tierwelt der Nord und Ostsee Begrundet von Grimpe und E Wagler Herausgegeben von G Grimpe Lieferung 15 Teil 9a *Aculifera*, von H J Nierstrasz und H Hoffmann, Teil 11 f *Thalassobionte* und *thalassophile Myriapoda*, von O Schubart, Teil 12h, *Pisces* Pp 64 + 20 + 141 + 164 (Leipzig Akademische Verlagsgesellschaft m b H, 1929) 8 80 gold marks

WITH the fifteenth *Lieferung* (12 h 3) of this work the portion dealing with the fishes ends, the present part consisting of an appendix dealing chiefly with distribution The fishes can now be obtained in a separate volume entitled " Die Fische der Nord- und Ostsee " In Part 9a (Aculifera), Drs N F. Nierstrasz and H Hoffmann give a good account

of the Aplacophora and of the Chitons In Part 11 f (Thalassobionta and thalassophile Myriapoda), Dr Otto Schubart describes the maritime and submaritime Myriapods There are a large number of the Aplacophora in this region, but although their anatomy is fairly well known, there is a lamentable gap in our knowledge of their development and life histories, the chief work on these having been done with species from elsewhere The same may be said of the Placophora, although more is known of this group and the eggs of a few of our common forms have been seen All the species are very clearly described and figured with details of the plates, so that identification should be easy, and the anatomy, biology, and distribution are fully discussed

The large number of myriapods which are more or less marine is surprising Most of these live on the shore between or above tidemarks, and they belong to several different groups Dr Schubart gives a very interesting account of these, especially with regard to their biology Some of them can remain alive under water many days, although not so long in salt water as in fresh, and in no case is it a natural habitat Damp, salty situations are by no means avoided, the chief localities being rocky and stony shores The internal anatomy is barely touched upon, but much space is given to the distribution and ecology of the species Most of the illustrations are original photographs or line drawings

A School Geometry By A Walker and G P McNicol Part 1 (Books I III) Pp viii + 256 3*s* 6*d* Part 2 (Books IV VII) Pp vi + 251-492 3*s* 6*d* Part 2, Section 1 (Books IV V) Pp vi + 251 352 2*s* Part 2, Section 2 (Books VI VII) Pp vi + 351 480 2*s* (London, New York and Toronto Longmans, Green and Co , Ltd , 1930)

THIS book is an improved version of the type of text book on elementary geometry that began to appear about thirty years ago It is carefully written and the supply of exercises is better than in some of the older books, but there is the traditional emphasis on 'bookwork' which seems somewhat out-of-date When examination papers in geometry consisted half of Euclid's propositions and half of riders demanding some real geometrical power, all that teachers could hope to do for their feebler pupils was to get them to understand enough about the subject to write out the propositions intelligently Nowadays, what is demanded is some power of independent thought sufficient to answer simple questions which, though they can scarcely be called riders in the old sense, are definitely not bookwork It is found possible to satisfy this demand save in very exceptional cases, and it can scarcely be doubted that the modern training is the more valuable

The process of learning propositions in a definite sequence, whether Euclid's or some other, comes nowadays later in the geometry course, and is not generally regarded as the matter of primary importance Therefore a text book arranged like this one, on traditional lines, is not probably the most convenient, especially for an inexperienced teacher who is perhaps doubtful about how the reading should be arranged

The printing and general arrangement of the book reflect the greatest credit on the printers and publishers A R

Leçons sur les systèmes d'équations aux dérivées partielles Par Prof Maurice Janet (Cahiers scientifiques, Fascicule 4) Pp viii + 125 (Paris Gauthier Villars et Cie, 1929) 30 francs

PROF M JANET has produced a valuable contribution to the analytical theory of partial differential equations It opens with a clearly written introduction in which are discussed the chief problems arising out of the general theory to be considered Then follow two chapters on " Calcul inverse de la dérivation ", existence theorems, and the linear partial equation of the second order in one unknown function These chapters lead logically to the development of the most important part of the subject with which the book is concerned, namely, the reduction of any system of equations to the canonical system of Riquier The final chapter is devoted to systems in involution, in which another canonical form is considered This is based upon M Cartan's development of the Pfaffian system

Numerous examples providing particular applications of the general theory are given Many of these are followed by interesting analytical notes Finally, valuable notes upon convergence of series solutions and the characteristic multiplicity of systems, together with a bibliographic summary for further reading, are given as an appendix

Plane Trigonometry By Prof J B Rosenbach and Prof E A Whitman Pp ix + 216 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 10*s* net

THIS is, in general, quite a well written book, though, in some respects, on old lines It covers elementary trigonometry to the logarithmic solution of triangles, and makes a good beginning by defining the functions of angles of any magnitude with the aid of co ordinates Circular measure is also developed early and used frequently throughout the text If, however, it is deemed necessary to devote a section to the theory and practical use of logarithms, there seems no reason for deferring such to the last chapter, especially when logarithms are freely used from Chapter ii onwards The section on the linear equation $a \cos \theta + b \sin \theta = c$ is not wholly satisfactory Greater emphasis should be laid on the introduction of irrelevant roots by squaring than is given in Ex 2 on p 108 The method of transforming to a quadratic in $\tan \frac{1}{2}\theta$ does not seem to be dealt with

There are plenty of good examples for which five figure tables are required, but some of the calculations involved are unnecessarily heavy The book is well printed, and answers to the examples are provided

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

The Ovary Stimulating Hormone of the Placenta

THE production of prematurity in young female rats and mice by Smith and Engle in America, and by Zondek and Aschheim in Germany, through the use of the anterior pituitary gland transplant or emulsion has afforded a great stimulus to further investigation of the hormonal control of gonadal activity The latter investigators have demonstrated that effects somewhat similar to those following pituitary gland implantations can be elicited in immature rats and mice by extract of pregnancy urine which has been rendered œstrin free They have likewise shown decidua, placenta, the corpus luteum of pregnancy, as well as pregnancy blood, to contain an ovary stimulatory hormone analogous to that of the anterior pituitary gland

Dr B P Wiesner, of the University of Edinburgh, experimented extensively with extracts of the placenta by the use of sulphosalicylic acid He is of the opinion that his own experiments have demonstrated the existence in placenta of two hormones, one of which he called 'Rho I', which is œstrogenic in action, causing prematurity phenomena in rodents, the other, 'Rho II', has a luteinising action on the ovary and causes a state of pseudo pregnancy (see Wiesner, *Edin Med Jour*, February 1930, p 73)

Dr Wiesner visited my laboratory in September 1929, and asked me to take up the problem of concentration and purification of the ovarian stimulatory hormone of placenta which he has termed 'Rho I' The problem was, therefore, made a subject of special study in this laboratory, and the results of our investigations to date, which appear to be of great interest, may be summarised as follows

1 The placenta (human or ox) contains an ovary-stimulating hormone the injection of which into immature rats and mice causes prematurity phenomena (Confirming Zondek and Aschheim, and Wiesner)

2 The active principle has been obtained in a fraction which is micro crystalline in character After repeated recrystallisations, 0 0015 mgm of such a fraction has been found to represent one rat unit

3 Active extracts which have been rendered protein- and lipoid free, as well as œstrin free have been standardised in terms of rat units The manifestation of prematurity phenomena (confirmed by microscopic sections of ovary, uterus, and vagina) has been the basis of the biological test

4 Active extracts have been shown to withstand *in vitro* digestion with pepsin and trypsin without appreciable loss of their physiological activity

5 It has been repeatedly demonstrated that potent extracts may be effective when administered by the oral route The amount of extract, administered orally, required to produce definite stimulation of the immature ovary may be very little more than the effective subcutaneous dose

6 The effects of daily injections, over long periods, of active extracts have been studied in relation to the histology of the genital tract and also in relation to pregnancy and lactation in the adult female rat

7. Immature female rats, as a rule, become cyclic following the induction of prematurity phenomena

8 Several instances of normal mating have occurred in treated rats thirty five to fifty days of age.

9 Adult rats which have received two to ten rat units daily have manifested the normal cyclic changes, have been impregnated and produced litters of normal size at the normal gestation period, and have shown no impairment of lactation Some of these rats are now in their third pregnancy since the injections began

10 Clinical trial of the placental extract in a selected group of cases of ovarian hypofunction, with the collaboration of Dr A D Campbell, has been productive of results which are most encouraging

This phase of our work at McGill University is now a subject of intensive study With the co operation of the staffs of the Royal Victoria and Montreal General Hospitals, the following types of cases are being studied

(*a*) Delayed puberty, (*b*) dysmenorrhœa, (*c*) amenorrhœa, (*d*) metropathia hæmorrhagica, (*e*) menopause, (*f*) toxæmia of pregnancy, (*g*) certain neurological and psychiatric cases, (*h*) thyroid dysfunction

The extract, in liquid form, is being administered by mouth

11 It is our opinion, in the light of experimental evidence, that the hormone of the placenta with which we are dealing is not identical with the anterior pituitary ovary stimulatory principle ('Rho I' of Wiesner) It is produced, we believe, by an active process in the placenta itself Its physiological effects on rodents are suggestive of the all or nothing law It will activate an immature or hypofunctioning ovary, but has little effect upon the normal organ, and no effect on a castrated individual

If we are correct in this assumption, then one should be able to demonstrate that the diseased placenta produces less of the active principle Assay experiments which are now being made on placenta, both normal and pathological, obtained at various periods of gestation, will do much to settle this point

The Crystalline Style of the Mollusca and a Carnivorous Habit cannot Normally Co-exist

THE crystalline style of the Lamellibranchs and many Gastropods consists of a gelatinous rod formed of protein of a globulin type It would, therefore, be readily digested by any extracellular proteoclastic enzyme in the alimentary tract Since the development of the carnivorous habit demands (with such rare exceptions as the one noted below) the presence of an enzyme capable of breaking down the flesh of the prey into soluble polypeptides and amino acids (for example, in Cœlenterates, Decapod Crustacea, and Cephalopods), it follows that a mollusc cannot normally both possess a style and be a carnivore

A brief survey of those molluscs which possess a style will emphasise this point The style is universally present in Lamellibranchs Here feeding is by ciliary mechanisms, the food being selected according to size only There is no extracellular protease in the gut, the only extracellular enzyme being that set free by the dissolution in the stomach of the head of the style and that acts exclusively on starch and glycogen (Yonge [1]) Zooplankton may survive passage through the gut Minute particles of animal matter (for example, blood corpuscles from fish) may be ingested and digested by wandering phagocytes which pass through the gut wall into the lumen and thence back

into the tissues More minute matter still may be digested intracellularly by the cells of the digestive diverticula The principal food of Lamellibranchs is fine phytoplankton

In the Gastropods the style is present in a variety of genera (see Robson [2] and Mackintosh [3]), but on examination these are seen to fall into two groups according to the mode of feeding There are (1) those that have ciliary feeding mechanisms and (2) those that scrape their food with a radula Examples of the first are provided by *Crepidula*, *Calyptræa*, *Capulus* (Orton,[4] Mackintosh,[3] Yonge[5]), *Vermetus* (which I have recently had the opportunity of examining on the Great Barrier Reef) and their allies among the Tænioglossa, and the Thecosomatous Pteropods (Yonge [6]) among the Tectibranchs In the latter case the gradual loss of the radula, jaws and 'salivary' glands handed down from carnivorous ancestors, in the series *Cavolinia*—*Cymbulia*—*Gleba*, with a simultaneous evolution of a more perfect ciliary feeding mechanism and of a small style (Meisenheimer [7]), is especially striking In the second class are included many 'scrapers' (Yonge [8]) of vegetable food, such as *Patella* in the Docoglossa, *Fissurella* in the Rhipidoglossa, and a variety of Tænioglossa including *Paludestrina*, *Turritella*, and *Aporrhais* (see Robson [2] and Mackintosh [3] for full list) Perhaps the best case is that of *Lambis* (Pterocera), which has a large firm style lying in a separate sac (Woodward [9]), the animal feeding by means of a delicate radula on the softest of filamentous weeds As I found in Australia, this animal has no extracellular protease in the gut, the 'salivary' glands are absent or degenerate, and is so specialised a herbivore as even to possess a powerful extracellular cellulase

The details of my investigations on reef molluscs will be published in due course

Passing to typical carnivorous Gastropods, very different conditions are found In *Natica*, *Murex*, *Pterotrachea*, and *Pleurobranchœa* (Hirsch [10]) there are in all cases powerful proteases in the alimentary canal secreted by the 'salivary' glands and possibly also by the digestive gland in the first two, and by the latter alone in the last two In *Sycotypus* (Mendel and Bradley [11]) the 'salivary' glands secrete a powerful protease, the secretion from the digestive gland being concerned only with the digestion of fats and carbohydrates

There is one exception which, to an unexpected degree, proves the rule The Septibranchs (Yonge [12]) have lost the ciliary feeding mechanisms of the other Lamellibranchs and developed a muscular feeding mechanism operated by the movements of the septum which enables them to swallow dead or dying animal prey, such as small Crustaceans, Annelids, etc The stomach has lost the sorting function it possesses in the other Lamellibranchs, has elongated, developed an interior horny lining and powerful circular and longitudinal muscles, and in this way become a crushing gizzard in which the prey is broken into fine fragments The small style is apparently practically functionless There is *no* free protease in the alimentary tract, the food particles being conveyed through the exceptionally wide ducts into the tubules of the digestive diverticula, where they are digested intracellularly

In my first paper on *Mya* (Yonge [13]) I attributed the dissolution of the style in the stomach to a secretion from the digestive diverticula of a protease I have since had a number of opportunities of correcting this error; the digestive diverticula of the Lamellibranchs do *not* secrete The style, as pointed out previously in these pages (Yonge [14]), which consists of an amphoteric protein, is solid at the low pH of its formation (4 5-5 8 according to the species), but dissolves in the less acid contents of the stomach, thereby releasing the enzyme and lowering the pH of the stomach contents to about the optimum conditions for the working of the enzyme (Yonge [5]) Its disappearance in animals where the style-sac is in free communication with the intestine is due to unfavourable conditions causing a decrease in secretory activity which is no longer able to keep pace with the process of dissolution

Summarising, it can be stated with confidence that the presence of a crystalline style in any mollusc is a certain indication that the animal in question possesses *no extracellular proteoclastic enzymes* and so cannot digest any but the very minute particles of protein matter which can be ingested intracellularly Such an animal is, therefore, except where a powerful crushing gizzard is present as in the Septibranchs, a specialised herbivore

Contamination by Dust Particles and Intensive Desiccation

As is stated by H B and M Baker in their 1912 article, it was a letter in regard to desiccated calomel that led them to study the effects of intensive desiccation on boiling points and other physical properties of liquids, a field in which the many investigators who have since entered it have obtained results that are outstandingly discordant In looking back at the work of Smith and Menzies, published in 1911, one can readily see that, in working with calomel, they were fortunate in being able to heat the substance to be desiccated for months at 115°, while the drying agent, in another portion of the same apparatus, could be kept at room temperature But one can recall also a feature of the work that is not obvious, namely, that, by reason of the methods used, their dry system was presumably unusually free from contamination with atmospheric dust Recent work in this laboratory has again brought to our attention the importance of atmospheric dust

One finds that salt hydrates show periods of induction, not only preceding the process of dehydration, as was remarked by Faraday and has been since confirmed by many others, but also preceding the processes of rehydration and of deliquescence This has been best observed with crystals grown from a state of lower hydration by gain of water from the vapour phase If such crystals are grown within a closed vessel, the conditions are favourable for the formation of a virgin surface, which refuses to be readily hydrated

Under suitable conditions the gain of water, once begun, proceeds with that change of rate through a maximum which is characteristic of an autocatalytic process This is in agreement with Langmuir's hypothesis, which, for this case, would state that the addition reaction which transforms the lower to the higher hydrate takes place only in the region where both the solid phases are in contact The presence

of the higher hydrate, the function of which may possibly be filled by other solids, isomorphous or otherwise, furnished by dust, promotes the reaction Dust may even furnish particles of salts that are deliquescent under the conditions of the experiment, thus making possible hydration of the salt studied by water in the liquid phase One could not, therefore, hope to observe, nor does one observe, the behaviour mentioned above if starting nuclei, furnished by dust, were thickly spread over the surfaces of the crystals of the lower hydrate In such a case, the induction period would be lacking and the rate of reaction a steadily diminishing one as the zone of reaction progressed, with diminishing area, toward the centres of the crystals, and this has been the common observation in the past The induction period observed, under suitable conditions, prior to combination with water, and the initial slowness of the process, may well explain the experimental findings reported in the literature concerning the unexpected inefficiency of such substances as anhydrous cupric sulphate or calcium oxide when used for the drying of gases

With reference to the effect of intensive desiccation on the boiling points of liquids, F O Rice has very properly considered the presence of dust as affecting superheating, although without illuminative result, and he pointed out further that dust particles present, if they also must be dried, will delay the drying of a system containing a liquid It may be added that certain substances contributed by dust particles may promote the changes under observation just as effectively as does water itself

One should recall, also, the independent and concordant findings of Wolski and of Kenrick that ordinary distilled water contains about 20,000 motes per cubic centimetre Other distilled liquids may be in like case Moteless water shaken in ordinary 'clean' glass apparatus rapidly acquires many motes Even dismissing from consideration the motes suspended in the liquid, one is able to bring forward additional reasons, beyond the mere sealing of capillaries, for timeously heating to the fusion point all glass apparatus designed for work on the effects of intensive desiccation For example, this fusion of the glass may flux and fix the loose scale that yields the motes, and will certainly enormously diminish the area of the quasi porous internal surface of glass that has been cleaned and roughened by cleaning solution Again, the fusion process may engulf and incorporate beneath a relatively plane glass surface dust particles of such ubiquitous salts as sodium chloride, as well as the ash of those organic particles which, in using Baker's air current technique rather than the vacuum technique for drying apparatus, have been burned to ash

Fuller reports of studies of these matters will appear elsewhere

The Green Flash in Southern California

Since my earlier letter on this subject (Nature, Aug 4, 1928) was written, I have made many more observations of the flash at sunset and many of the flash at sunrise Most of the flashes at sunset have been seen from our former residence on a hill near the old campus of the University, from our present residence and the new campus itself in Westwood Hills, from the streets of Los Angeles, and from the beaches near Los Angeles, as the sun has set over the Santa Monica Mountains, Santa Catalina Island, the ocean, or clouds lying low above the ocean or mountains All but one of the flashes at sunrise have been seen from Westwood Hills as the sun has risen over the Baldwin Hills and other elevations east and south east, while one of the most beautiful was seen from a peak on the eastern rim of Death Valley

The observations of these beautiful but variable phenomena have been very numerous Usually no record has been kept, but in the 32 day interval Aug 20–Sept 20, 1928, I witnessed the flash at sunset 13 times, and I am confident that I have since seen a greater number of sunset and sunrise flashes in an interval no greater In the 32 days referred to, fogs and clouds interfered on 9 days, the back ground of sky was too bright on 3 days, observations could not be made on 5 days, although it is practically certain that the flash would have been seen on some of these days if it could have been looked for, and on 2 days the flash was not seen when conditions were judged favourable for its appearance It is probable that the flash was seen also on one of the days mentioned above as having too bright a sky On this occasion three observers in Tujunga watched the sun set over the Verdugo Hills, which were too close and too high for satisfactory observation, and two out of the three reported that they saw the flash On account of the numerous fogs and cloudy horizons at the beaches here, it is usually easier to get the flash over the mountains or hills than over the ocean, since the elevations are likely to be high enough to be out of the fog and low enough and remote enough to give sufficient dispersion

I have repeatedly witnessed the transition between the blue and the green of the flash, and also the yellowish green of the upper portion of the sun which often precedes the flash at sunset and follows it at sunrise

Contrary to what appears to be the usual impression, the green flash is at least as easy to observe when the sun is considerably reddened as when it is bright I have sometimes been surprised that the sun could be so red and yet have sufficient green left to show the flash The blue, of course, does not appear in such circumstances

Many of the observations referred to, including one of the most brilliant, have been over low lying clouds On one occasion I saw the sun flash green first over the top of a cloud, and then, a little later, through a hole in the cloud

On a number of occasions I have seen double flashes as the sun has set, first over a low lying cloud and shortly afterward over the ocean beneath, and on one occasion I witnessed what I believe to have been a triple flash, as follows The sun first set over a low cloud and flashed green, then it set over the sea beneath and flashed green, and finally the light reflected from the lower surface of the cloud to the sea turned green before it disappeared

Taxonomic Importance of the Terminal Segments of Psychodid Larvæ

Although in the last quarter of a century a considerable amount of advance has been made in various parts of the world towards the classification and morphology of the imago of the family Psychodidæ, our systematic knowledge of the immature stages of the group is surprisingly scanty This is perhaps due in the first place to the secluded nature of the breeding places of the members of this family, and secondly to the fact that, unless and until the complete life history of each species is studied thoroughly in the laboratory,

one is not in a position to place an egg, a larva, or a pupa to a particular species. While engaged in the breeding of sandflies at the Kala-azar Research Laboratory of the Calcutta School of Tropical Medicine and Hygiene, I had an excellent opportunity of studying the immature stages and more especially the larvæ of the species occurring locally.

During a course of systematic study of the larvæ bred from strains of known species, I found that the specific differences are prominently confined to the two terminal segments in the case of the genus *Phlebotomus* and only to the last segment in the case of the genus *Psychoda*. Owing to the semi-aquatic nature of environment adapted by *Psychoda* larvæ, the terminal segment becomes modified into a tubular structure with the spiracular openings arranged at its tip; specific variation was also observed in the case of the sclerites surrounding the anal pore. The *Phlebotomus* larvæ, on the other hand, are remarkably terrestrial (with a series of pseudo-legs), and with the modification of the sclerites of the dorso-ventrally flattened terminal segment admirably adapted as an adjunct organ of locomotion in the larvæ as well as a fixing structure for the pupæ, the posterior pair of spiracles becomes shifted to the penultimate segment in the larvæ. The structural modifications of the terminal segments of two genera and five species occurring locally have been studied by me and my classification is based on the variable nature of these structures. The following genera and species have been studied: Genus *Psychoda*; *Psychoda bengalensis* Brun.; *Psychoda plumosa* sp. nov.; Genus *Phlebotomus*; *Phlebotomus argentipes* Ann. and Brun.; *Phlebotomus papatasii* Scop.; and *Phlebotomus* (*babu*) *minutus* Rond.

A detailed work on this line is in progress and will be published elsewhere.

Integration of Sunlight in the Tropics

A PHOTO-ELECTROLYTIC method of integrating sunlight has been described by Atkins and Poole (*Proc. Roy. Dub. Soc.*, vol. 19, p. 159). The electric current in a photo-electric cell is proportional to the light falling on it, and the latter can be integrated over any period of time, by measuring electrolytically the total quantity of electricity that passes through a sensitive voltameter in series with the cell. In Dublin, where this method of sunlight integration has been carried out, the average illumination for a bright sunny day in November was estimated as 10,000 metre candles for ten hours.

Using a modified form of the apparatus, which will be described elsewhere, similar investigations have been carried out by us in Rangoon. The observations were made during the early part of November, and it may be of interest, for comparison purposes, to record the results which have been obtained during one week, when the illumination from day to day was decidedly variable. With the apparatus employed a deposit of 8.81×10^{-10} gm. of copper corresponds to an average illumination of 500 m.c. for one second, and the light was integrated each day over a period of six hours.

For bright sunny days, the copper deposited varied from 9.9 mgm. to 12.4 mgm., corresponding to an average illumination of about 250,000 to 325,000 m.c. A day of variable sunlight gave a deposit of 4.9 mgm. corresponding to an average illumination of 125,000 m.c., whilst the illumination on a particularly dull day was about 60,000 m.c.

In the British Isles an average of 50,000 m.c. is quoted as a reasonable figure for a twelve-hour bright summer's day, which appears to be about the same as that obtained by us over a shorter period, during a particularly dull day in the tropics, whilst the average illumination over a sunny day in the tropics is considerably in excess of the maximum illumination attained during a summer's day in the British Isles, which is quoted as reaching approximately 150,000 m.c. A method is being devised of increasing the sensitivity of this method of sunlight integration, so as to obviate the necessity of employing very sensitive methods of chemical analysis, which is a disadvantage when a great number of records are being made.

It is intended to make a complete study of the illumination at different times of the year, and, under various conditions, also to record diurnal variations in the illumination.

The Gibbs-Ewald Reciprocal Lattice

As I received no proof of the note appearing under the above title in NATURE of Feb. 15, p. 238, I wish here to correct certain misprints and to make some slight modifications which would otherwise have been made in the proof.

In line 7, for K read k, and in the equation in line 14, read for l, the exponential e. The distance between any two adjacent planes is of course $n/(u_1^2+u_2^2+u_3^2)^{\frac{1}{2}}$. [The fractional index was omitted from the original letter.—Ed., NATURE.]

In the penultimate paragraph, I wish to delete all but the first sentence, and to substitute the following: "With the usual summation convention we write

$$e^{2\pi i u_i x^i} = 1,$$

both sets of co-ordinates being referred to an affine system of oblique axes[2] of constants a, b, c, and angles α, β, γ, appropriate for the crystal under consideration." In accordance with this modification the transformation equation of the last paragraph would then read $F(u_i x^i) = 0$.

A Superconducting Alloy with Resistance Temperature Hysteresis

IN some experiments made in collaboration with J. F. Allen and J. O. Wilhelm, we found that the resistance of a ternary alloy of bismuth, lead, and tin dropped slowly with temperature in the usual manner down to 9° K., where it suddenly fell to zero. On raising the temperature, the alloy remains superconducting up to a temperature of 13.2° K., at which point the resistance reappeared and rose quickly to a steady value at 13.8° K. This would appear to be the first time that a resistance temperature hysteresis effect has been observed and measured.

University of Toronto.

Early Man in China.

By Prof G ELLIOT SMITH, F R S

THE reconnaissance inaugurated in 1921 by Dr J G Andersson on behalf of the Geological Survey of China has brought to light evidence of exceptional interest and importance for students of archæology and human palæontology In the province of Honan, Dr Andersson discovered a rich industry, including painted pottery, the cultural link of which with ancient Sumer is widely admitted It provides positive confirmation of the early diffusion of culture from Mesopotamia to the eastern limits of Asia during the third millennium B C In addition, he recovered a number of interesting human remains in association with the early industries in Honan and Kansu His survey has also been responsible for the discovery of the fossil remains of the early Pleistocene genus of the human family which Prof Davidson Black called *Sinanthropus*—roughly contemporaneous with *Pithecanthropus* and *Eoanthropus*

(1) In *Palæontologia Sinica* (Series *D*, Vol 6, Fasc 1) Prof Davidson Black has completed the statistical investigation of the Kansu and Honan skulls found with the painted pottery and has compared them with specimens from later Kansu prehistoric sites as well as with more recent crania from northern China and elsewhere In this laborious work, he has followed the mathematical methods devised by Prof Karl Pearson and his school The interest and value of this elaborate monograph is not diminished by the fact that the results obtained fully confirm those announced in 1925 from simple observation, before Dr Black had begun the statistical analysis of the material He has now established the fact that the prehistoric population of eastern Asia in the third millennium B C was sufficiently akin to the modern inhabitants of northern China to justify the application to them of the term 'proto-Chinese' He notes, further, that the earlier members of his series diverge much more widely from the modern type than do those of the later prehistoric phases of culture In certain suggestive features the earliest types present some near resemblances to the Khams-Tibetan type described by Dr Morant

(2) Prof Davidson Black is to be congratulated on the promptitude with which from time to time he has placed at the disposal of anthropologists the information relating to the various discoveries of fossil remains of *Sinanthropus* The "Preliminary Note on Additional Sinanthropus Material" issued in the *Bulletin of the Geological Survey of China* (Vol 8, No 1, 1929) deals with the material found in the autumn of 1928 at Chou Kou Tien in the course of excavations carried out by Dr Birger Bohlin, Dr C C Yong, and Mr W C. Pei Previous to this discovery, the new genus was known only from a few teeth, but in 1928 the excavators found, in the neighbourhood of the place where the tooth-type had been recovered in the previous year, the greater part of the right horizontal ramus of an adult lower jaw with three molar teeth *in situ*, and the sockets of the premolar, canine, and distal half of the lateral incisor preserved In addition, more than twenty teeth, both deciduous and permanent, representing many phases of wear and differences in age, were found, together with the front part of the lower jaw of a child The fragments of jaws, adult and infantile, were embedded in blocks of travertine, and at the time the report was published the associated cranial fragments had been only incompletely freed from the stony matrix The piece of the child's jaw was intimately associated in the block of travertine with a parietal bone of corresponding age Although this part of the braincase had not been extracted from the matrix, sufficient of it was visible to enable Dr Davidson Black to say that it was definitely human in type and represented part of a roomier braincase than that of *Pithecanthropus*

The importance of this association of part of a human skull with a fragment of jaw of corresponding age is of special interest because the jaw presents simian peculiarities of conformation such as, in the case of the Piltdown jaw, aroused in the minds of many foreign palæontologists doubt as to the possibility of association with a human skull The present report, providing more than forty photographs and skiagrams of the new specimens, and comparative data to permit an exact comparison with known specimens, makes it possible for anthropologists throughout the world to appreciate the exact nature of the material which has been found and to estimate its vast significance

This discovery justified Prof Davidson Black's bold action in creating a new genus on the evidence of a tooth The far-reaching importance of the fossils found in 1928 is enhanced by the even more startling discovery made on Dec 2, 1929, by Mr W C Pei, of a complete braincase of an adult skull of *Sinanthropus*, which is uncrushed This new specimen is unique it is the only complete braincase of early Pleistocene man so far known It brings home in a much more convincing way than the recovery of mere fragments, the reconstruction of which invariably excites suspicion in the minds of most people, the tremendous significance of the discoveries in China For this braincase is more complete than the remains of either *Pithecanthropus* or *Eoanthropus*, and, contrary to the anticipations which were made last year (when a jaw was found presenting features hitherto unknown in any other human remains except *Eoanthropus*), displays a form more nearly akin to the Javanese than to the Piltdown fossil

The photograph recently received in England, reproduced as Fig 1, represents the skull in the state it reached the laboratory in Peking The base is still embedded in plaster of Paris and the occipital bone is hidden almost as far as the lambda.

In the accompanying diagram (Fig 2), made by Miss Eleanor Dale, the contour of the part of the skull of *Sinanthropus* displayed in the photograph

is shown by the line *A* The dotted line is merely a tentative suggestion of the form of the skull with a drawing of the fragment of an adult jaw found in 1928 The contours of the cranial vaults of *Pithecanthropus* (*B*) and the type specimen of Neanderthal man (*C*), both presenting analogous forms, have been inserted for comparison, the inch-scale providing the criterion of exact size Its resemblance to the Neanderthal skull is discounted by the significant difference in actual size

With the photograph Prof Davidson Black has sent the following information

Within the main cave deposit at Chou Kou Tien, up to the present time, *Sinanthropus* remains have been recovered from five different sites, three of which, including the latest, have been discovered by Mr Pei during the last season's work Contrary to the reports which have been circulated, no skeletal parts other than the skull and numerous isolated teeth have been recovered during this year's excavations Remains of at least ten individuals belonging to the genus have been found

It should be noted that the different sites where

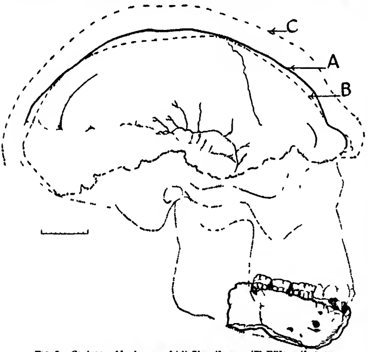

FIG 2 —Contours of brain-case of (*A*) *Sinanthropus*, (*B*) *Pithecanthropus*, (*C*) Neanderthal man.

Sinanthropus has been discovered within the main Chou Kou Tien deposit are all clearly contemporaneous with one another, being Lower Quaternary (Polycene) in age. This statement is based on the investigations of Père Teilhard de Chardin and Dr C C Yong on the geology and palæontology Though hundreds of cubic metres of material have

FIG 1 —Brain case of *Sinanthropus*

been examined, no implements or artefacts of any nature have been found, nor has any trace of the use of fire been observed

The greater part of the left side and the fore part of the base of this unique braincase of *Sinanthropus* is still embedded in a block of very hard travertine The vault of the skull from its massive brow ridges to the occiput, and the whole right side of the specimen was, however, encrusted with a relatively soft matrix, which was removed before the photograph was taken It is apparent that the braincase has been almost completely preserved while most of the facial region seems to be lacking

The skull of *Sinanthropus* is of approximately the same length as that of *Pithecanthropus* and, like the latter, is provided with massive brow ridges However, *Sinanthropus* differs from the Java type in the following important features Relatively well-developed frontal eminences, well-localised parietal eminences, and greater height of skull vault, all these characters pointing to a relatively greater brain capacity in *Sinanthropus* The mastoid processes are small and rugged The sockets in which the lower jaw articulated are well preserved on both sides, a circumstance which will be of great value when the task of reconstructing the lower jaw (shown in Fig 2), recovered in 1928, is undertaken

Discovery of a Trans-Neptunian Planet.

By Dr A C D Crommelin

On the evening of Mar 13 (an appropriate date, being the anniversary of the discovery of Uranus in 1781, and Mar 14 being the birthday of the late Prof Percival Lowell) a message was received from Prof Harlow Shapley, director of Harvard Observatory, announcing that the astronomers at the Lowell Observatory, Flagstaff, Arizona, had been observing for seven weeks an object of the fifteenth magnitude the motion of which conformed with that of a planet outside Neptune, and agreed fairly closely with that of one of the hypothetical planets the elements of which had been inferred by the late Prof Percival Lowell from a study of the small residuals between theory and observation in the positions of Uranus That planet was better suited than Neptune for the study, since the latter had not been observed long enough to obtain the unperturbed elements

Lowell's hypothetical planet had mean distance 43 0, eccentricity 0 202, longitude of perihelion 204°, mass 6½ times that of the earth, period 282 years, longitude 84° at the date 1914–15 Its position at the present time would be in the middle of Gemini, agreeing well with the observed place, which on Mar 12 at 3h U T was 7 seconds of time west of δ Geminorum, the position of the star was R A 7h 15m 57 33s, north decl 22° 6′ 52 2″, longitude 107 5° This star is only 11′ south of the ecliptic, making it likely that the new planet has a small inclination As regards the size of the body, the message states that it is intermediate between the earth and Uranus, implying perhaps a diameter of some 16,000 miles A lower albedo than that of Neptune seems probable, to account for the faintness of the body It appears from a New York telegram that at least one visual observation of the planet has been obtained, from which the estimate of size may have been deduced

Mention should also be made of the predictions of Prof W H Pickering, one of these, made in 1919 (*Harvard Annals*, vol 61), gives the following elements, Epoch 1920, longitude 97 8°, distance 55 1, period 409 years, mean annual motion 0 880°, longitude of perihelion 280°, perihelion passage 1720, eccentricity 0 31, perihelion distance 38, mass twice earth's, present annual motion 0 489° This prediction gives the longitude for 1930 as 103°, which is within five degrees of the truth, actually it was in longitude 108° at discovery Prof Pickering's later prediction is further from the truth, making the longitude about 131°

Gaillot and Lau also made predictions, like the other computers they noted that there were two positions, about 180° apart, that would satisfy the residuals almost equally well Taking the position nearest to the discovered body, Lau gave longitude 153°, distance 75, epoch 1900 Gaillot gave longitude 108°, distance 66, epoch 1900 The latter is not very far from the truth, with a circular orbit, the longitude in 1930 resulting from Gaillot's orbit would be 128°, some 20° too great Gaillot performed the useful work of revising Le Verrier's theory of Uranus, thus giving more trustworthy residuals Lowell pointed out that the residuals of Uranus that led to the discovery of Neptune amounted to 133″, while those available in the present research did not exceed 4 5″, yet even in the case of Neptune the elements of the true orbit differed widely from the predicted ones, though the direction of the disturbing body was given fairly well He noted that in the present case it would be wholly unwarrantable to expect the precision of a rifle bullet, if that of a shot gun is obtained, the computor has done his work well

Another method of obtaining provisional distances of unknown planets is derived from periodic comets, the mean period of the comets of Neptune's family is 71 years, it is pointed out in the article on comets (" Encyc Brit " 14th edition, vol 6, p 102) that there is a group of five comets the mean period of which is 137 years, as stated there, " This family gives some ground for suspecting the existence of an extra-Neptunian planet with period about 335 years, and distance 48 2 units " This seems to be in fair accord with the new discovery, but probably the distance is nearer 45 than 48 Comets also suggest another still more remote planet, with period about 1000 years, a suggestion which has also been made by Prof G Forbes and by Prof W H Pickering

The question has been asked, " Does the new planet conform to Bode's law ? " It is difficult to assign a definite meaning to this question, since Bode's law broke down badly in the case of Neptune, Neptune's predicted distance was 38 8, its actual distance 30 1 For Bode's law, each new distance ought to be almost double the preceding one, the constant term of the law becomes negligible when the distance is great, For the extension of the terms given by the law we might (1) ignore Neptune as an interloper and take the next distance as double that of Uranus, giving 38½ units, (2) we might take the next distance as four times that of Uranus, which would give 77 units, or (3) we might take the next distance as double that of Neptune or 60 units, none of these values is good, but (1) is the nearest to what we suppose to be the distance Probably the best course is to assume that after Uranus the law changes, each new distance is then 1½ times the preceding one, on this assumption, the hypothetical planet with distance 100 and period 1000 years would be the next but one after the Lowell planet

The low albedo of the new planet might be explicable if its temperature were much lower than that of Neptune Owing to its smaller size, it would have lost more of its primitive heat, and would only receive half as much from the sun, hence its gases might be reduced to a liquid form, with great reduction of their volume This would result in a relatively smaller disc than the one that might be inferred from its mass

Some further particulars of the discovery are given by the New York correspondent of the *Times* in the issue for Mar 15 Quoting an announcement which had been received there from the Lowell Observatory, it is stated that the planet was discovered on Jan 21 on a plate taken with the Lawrence Lowell telescope, it has since been carefully followed, having been observed photographically by Mr C O Lampland with the large Lowell reflector, and visually with the 24 inch refractor by various members of the staff The observers estimate the distance of the planet from the sun as 45 units, which would give a period of 302 years, and mean annual motion of 1 2 degrees

At discovery, the planet was about a week past opposition, and retrograding at the rate of about 1′ per day, this has now declined to ½′ per day, and the planet will be stationary in April It should be possible to follow it until the middle of May, when the sun will interfere with observation until the autumn

The details of the Lowell Observatory positions have not yet come to hand, when they do, it will be possible to derive sufficiently good elements to deduce ephemerides for preceding years There are many plates that may contain images of the planet, those taken by the late Mr Franklin Adams in his chart of the heavens, those taken of the region round Jupiter some twelve years ago for the positions of the outer satellites, and those taken at Königstuhl and elsewhere in the search for minor planets, these all show objects down to magnitude 15 If early images should be found, they will accelerate the determination of good elements of the new planet, in the case of Uranus, observations were found going back nearly a century before discovery, and in that of Neptune they went back fifty-one years In the present case, forty years is the most that can be hoped for, and probably very few photographs showing objects of magnitude 15 are available before the beginning of this century

One of the most difficult problems will be to find the mass of the new body, in Neptune's case, Lassell discovered the satellite a few months after the planet was found, and the mass was thus determined It is to be feared, however, that the new planet would not have any satellite brighter than magnitude 21 Stars of this magnitude have been photographed with the 100-inch reflector at Mount Wilson, but it is doubtful whether it could be done within a few seconds of arc of a much brighter body Failing the detection of a satellite, the mass can only be deduced from a rediscussion of the residuals of Uranus and Neptune, new tables of these planets will ultimately be called for, but that task must wait until the orbit of the new body is known fairly exactly

The perturbations of Halley's comet will also require revision, at each of the last two returns, there has been a discordance of two or three days between the predicted and observed dates of perihelion passage, it will be interesting to see whether the introduction of the perturbations of the new body effects an improvement The late Mr S A Saunder made the suggestion at the time of the last apparition of the comet that an unknown planet might be the cause of the discordance, but it was not then possible to carry the suggestion further The discovery of a new planet therefore opens a large field of work for mathematical astronomers It will also appeal to students of cosmogony, Sir James Jeans, in an article in the *Observer* for Mar 16, suggests that it may represent the extreme tip of the cigar shaped filament thrown off from the sun by the passage of another star close to it It would have been the first planet to cool down and solidify, he says, "As a consequence of this, it will probably prove to be unattended by satellites"

Lowell's Prediction of a Trans-Neptunian Planet

By Dr J Jackson

THE reported discovery of a planet exterior to Neptune naturally arouses the interest of the general public It will be of importance in theories concerning the genesis of the solar system as to how far it falls into line with the other planets as regards distance, mass, eccentricity and inclination of orbit, and presence or absence of satellites Its physical appearance will be beyond observation To those interested in dynamical astronomy, it may be of some interest to consider the data which led to its discovery and to make some comparison with the corresponding facts relating to Neptune

If the planet which has been reported approximately follows the orbit predicted by Dr Percival Lowell, the prediction and the discovery will demand the highest admiration which we can bestow It is true that the problem as regards its general form is a repetition of that solved by Leverrier, Adams, and Galle more than eighty years ago, but its practical difficulty is of quite a different order of magnitude In short, this discovery, if it turns out to be actually Lowell's predicted planet, was extremely difficult—while Neptune was in fact crying out to be found Let us look at the actual data

Uranus was discovered in 1781 by Herschel Scrutiny of old records showed that it had been observed about a score of times dating back to 1690 The fact that Lemonnier observed it eight times within a month, including four consecutive days, without detecting its character, should be a lesson to anyone who makes observations without examining them In 1820 Bouvard found that the old and the new observations could not be reconciled, and in constructing his tables boldly rejected the early observations, but the tables rapidly went from bad to worse, the residuals amounted to 20″ in 1830, 90″ in 1840, and to 120″ in 1844. Adams used in his first approximation data up to 1840, Leverrier data up to 1845 Now Uranus had passed Neptune in 1822 As the relative motion is about 2° a year, it means that for most of the time covered by the prediscovery observations the perturbations were very small, while from the fact

that the difference between the heliocentric distances is much smaller than expected from Bode's law, the perturbations at the time of conjunction were relatively large Consequently the prediction of the longitude of the disturbing body was very easy, while the determination of the other elements were correspondingly difficult The fact was that the simple hypothesis of the existence of an exterior planet with any sort of guess as to size and shape of orbit would suffice to predict the longitude In other words, most of the residuals could be closely satisfied provided that substantially correct values of the longitude of the planet and its attractive force $m\left(\frac{1}{\Delta^3}-\frac{1}{r^3}\right)$ were used Both Leverrier and Adams easily found values of these quantities, and Galle had no difficulty in detecting the planet

We now turn to Lowell's "Memoir on a Trans Neptunian Planet", published in 1915 The observational basis is the outstanding residuals in the motion of Uranus during two centuries, that is, rather more than two revolutions of that planet round the sun, of somewhat less than two revolutions relative to the predicted planet and of about one relative to Neptune The following are the values of the observed residuals of Leverrier's and of Gaillot's theories taken from Lowell's memoir

	Leverrier	Gaillot		Leverrier	Gaillot
1709		+2 14″	1855		−0 50″
1753	+5 52″	+4 45	1858	+0 50″	−0·20
1769	+4 77	+2 47	1861		−0 36
1783	−3 30	−0 96	1864	+0 25	+0 18
1787	−5 12	−1 20	1867		+1 20
1792	−3 50	+0 10	1870	−0 50	+1 32
1796	−1 88	−0 69	1873		+0 75
1803	+0 40	−1 19	1876	−1 65	−0 50
1812	+2 00	−0 77	1879		+0 58
1817	+0 50	−0 60	1882	−2 88	+0 52
1820	−0 75	−2 37	1885		−0 17
1827	−2 10	+2 00	1888	−4 22	−0 85
1837	−1 10	−1 22	1891		−1 11
1840	+0 63	+0 78	1894	−5 63	−0·50
1843		+0·74	1897		+0 35
1846	+0·38	−1 40	1900	−4 32	+1 00
1849		−0 25	1903	−3 00	+0 65
1852	−1 17	−0 95	1907		+0 25
			1910		+1 10

The residuals show remarkable differences between the two theories, but Lowell deduced that the residuals exceeded their probable errors four or five times The problem was to find from these residuals corrections to the elements of the orbit and to find the mass and the elements of the disturbing body It might almost appear hopeless when we consider that the residuals must be affected by errors in the accepted masses of the known planets There can be no doubt, however, that the masses adopted by Gaillot for Jupiter, Saturn, and Neptune are very accurate Lowell's procedure was to adopt a value of the semimajor axis of the unknown body, and a complete series of values for its longitude, and then select the value of the longitude for which the sum of the squares of the residuals was a minimum The process was repeated with various values of the mean distance until values of the variables were found giving minimum residuals The process was of course very laborious, but Lowell carried it through with great perseverance The following extract from his final summary may be quoted "By the most rigorous method, that of least squares throughout, taking the perturbative action through the first powers of the eccentricities, the outstanding squares of the residuals from 1750 to 1903 have been reduced 71 per cent by the admission of an outside disturbing body"

The inclusion of further terms, of additional years and of the squares of the eccentricity, do not alter the results by any substantial amount Lowell considered that the remaining irregularities could be explained by errors of observation No trustworthy results could be found from the residuals in latitude so that the inclination of the orbit to the ecliptic could not be deduced, but Lowell considered that it might be of the order of 10°

As the solution really depends on the difference of the attraction of the unknown planet on Uranus and on the sun, there are two possible solutions in which the longitudes differ by about 180° The following elements are for the solution satisfying most nearly the position of the newly found body

Heliocentric longitude on 1914, July	84 0°
Semimajor axis	43 0
Mass in terms of the sun's mass	1/50,000
Eccentricity	0 202
Longitude of perihelion	203 8°

This gives the longitude at the present time as about 104° compared with 107° of the new planet The predicted magnitude was 12 to 13 or about ten times brighter than the observed, and a disc of more than 1″ was predicted This is a rather serious discordance

The smallness of the residuals indicated that the forces were small The mass given above is only 0 4 of the mass of Neptune At mean conjunction, the attraction of the predicted planet on Uranus would be only one-fifteenth of the attraction of Neptune in a similar position, and in addition it would last for a shorter time on account of the more rapid relative motion

The discovery of a minor planet of the fifteenth magnitude is an everyday occurrence The planet reveals itself by a decided motion relative to the stars in the course of taking a photograph For a planet in the predicted orbit, the motion shown (mostly due to the earth's motion) would in the most favourable circumstances not be more than 2″ or 3″ an hour, and it would probably need a trail of at least 5″ for the planet to be detected On the other hand, photographs taken on successive days would show decided motion, but the labour of finding the planet in a region containing many thousands of stars from separate photographs would be very great Probably the Lowell observers have come across several minor planets before they were rewarded by the discovery of the very distant planet.

Astronomers all the world over will naturally look forward with great interest to see how nearly the newly discovered body moves in the orbit predicted by Lowell, and are anxiously waiting for further details of the observations.

The Problem of Stellar Luminosity

SIR JOSEPH LARMOR, who raised certain interesting points concerning the validity of my recent work on stellar luminosity in NATURE of Feb 22, has kindly allowed me to see some further exposition on these points which he proposes to publish in the *Observatory* With his further analysis of the situation I am in complete agreement As regards the question which he thinks still outstanding, the work of Sir James Jeans and of J Woltjer, together with my own investigations, shows that $1-\beta$, the ratio of radiation pressure to total pressure varies very slowly in the photospheric layers of a star on plausible assumptions as to the absorption coefficient It therefore satisfies his requirement of being independent of the precise surface at which it is evaluated But it is necessary to explain the discrepancy with other existing theories

All formulæ so far given for the luminosity of a star are cooling formulæ They take different forms according to the data Thus given the radius r_1 and the actual temperature T_1 of the photosphere, the cooling L is at the rate $4\pi r_1^2\sigma T_1^4$ Given the mass M, the relative density distribution, the surface opacity and T_1, we have the formula given in my paper (p 38) which is due in principle to H Vogt Given the mass, the relative source distribution, and the internal opacity, we have a formula due to Prof Eddington, which he has transformed into forms involving T_c (the central temperature) and T_e (the effective temperature) The problem is, however, something much more deep seated than a mere cooling problem The complete solution of the problem would predict the luminosity of a given mass M when in a steady state, given simply the physical properties of the matter composing it, without any other astronomical data This problem is so far completely unsolved Though Prof Eddington has pictured the astronomer on the cloud bound planet as being capable of predicting the luminosities of the unseen stars, he would in fact be completely incapable of predicting them at all, for he would not have the slightest idea as to what to expect for their effective temperatures, and the effective temperature is an additional astronomical datum which requires to be given before Eddington's formulæ become applicable The cloud bound astronomer would be quite incapable of foretelling the observed mass luminosity relation—the confining of the stars to a narrow band in the plot of luminosity against mass

When we attempt to probe more deeply into the problem of stellar luminosity and effective temperature, using Eddington's theory as a basis, we encounter difficulties so serious that in my opinion they can only be removed by abandoning one feature of Eddington's method of approach That theory makes luminosity 'depend' on interior opacity But how can the opacity (a property depending on outer electronic configuration) affect the unknown subatomic generation of energy? According to his formulæ, if we change the opacity we change the luminosity But the only way in which opacity can have a physical effect is by altering the internal temperature, and thus it would appear that the theory involves a specific dependence of rate of generation of energy on temperature, whereas no such dependence has been explicitly woven into the theory No formula is given which determines the (effective or central) temperature of a given mass in terms of purely physical (that is, non astronomical) data Eddington's equations are incomplete They are one short The missing equation is easily supplied It is $L=\int\epsilon dM$, where ϵ is the rate of generation of energy per unit mass The satisfaction of this condition is not automatically provided for in Eddington's scheme of equations

The internal contradictions that arise may be illustrated as follows It is stated that his special model is most accurate (on the physical theory of opacity) when the generation of energy is proportional to the temperature T at any point Put then $\epsilon=\lambda T$ Either λ depends solely on the physical properties of matter and is then an atomic constant, or it depends on the past history of the material Consider first the former alternative It gives $L=\lambda\int TdM=\lambda M\bar{T}=\lambda M\times 0\,584T_c$ Combining with Eddington's formula $L=\text{const}\times M(1-\beta)^2\beta^{-1}T_c^{\frac{1}{2}}$, we find $T_c=\text{const}\times(1-\beta)^4\beta^{-2}$ where the first factor is a purely physical constant This would make T_c an increasing function of mass, contradicting the 'observed' constancy of T_e along the main series Combining this again with his formula $T_e\propto M^{-\frac{1}{4}}(1-\beta)^{-\frac{1}{4}}T_c^{\frac{1}{2}}$ where T_e is the effective temperature, we find $T_e^{\frac{1}{2}}\propto M(1-\beta)\beta^{2}$ This makes T_e an increasing function of mass, contradicting the simultaneous existence of giants and dwarfs of widely different mass but the same effective temperature (Any formula of the type $\epsilon=\lambda\rho^a T^b$ will be found to lead to a similar contradiction)

We are then driven back on the second alternative, that λ depends on the past history of the material and so may be different for different stars This is the 'exhaustion effect' But now the exhausted material may distribute itself in any way through the non exhausted energy generating material There will in general be a concentration gradient of the latter with respect to the former through the star, and though $\epsilon=\lambda T$ may describe the nature of the concentration gradient, this no longer implies a physical dependence of ϵ on temperature The energy generating material may even generate energy at a rate independent of temperature, and be simply distributed through the 'dead' material so as to mimic the distribution $\epsilon=\lambda T$ We are now compelled, since a hard and fast dependence of ϵ on T and ρ is ruled out, to consider the other extreme, the 'uranium' model of Jeans, with local energy generation independent of temperature (or of course any intermediate model) But the problem cannot now be studied by Eddington's method This method *begins* with the relative source distribution (his η) The problem now becomes given a mixture of x grams of uranium (or other radioactive material)

and y grams of calcium (or other 'dead' material), How do the x grams of uranium distribute themselves through the y grams of calcium? The relative source distribution, which in Eddington's analysis is a datum of the problem, now becomes an unknown which has to be determined The luminosity, in Eddington's analysis an unknown, becomes a datum

According to his "Internal Constitution of the Stars", Eddington would meet this difficulty in two ways He contends first that the uranium model is unstable, secondly that the luminosity (for equilibrium) is roughly independent of the source distribution η The following considerations show that neither of these contentions can be accepted In the first place, he argues that if the total rate of generation L' falls below the rate of cooling L, the star will contract indefinitely (p 303), since according to him L increases as the star contracts But, as pointed out by Jeans, this involves the assumption that a formula derived for a special model in equilibrium holds generally Physically a star cannot 'contract indefinitely' It cannot *vanish* Physical intuition of the valid kind tells us that sooner or later the star must find a (contracted) configuration of equilibrium, each element, being supplied with energy at a rate less than its momentary rate of cooling, must cool until the two balance, the energy it gains from compression will simply enable it the sooner to arrive at this state A cooling element cannot cool at an increasing rate as it cools

Similar considerations show that the luminosity of a star cannot be even roughly independent of the relative distribution of energy sources, when we consider the distribution as a datum and the luminosity as a dependent variable Eddington has offered as proof of his contention a special solution of the point source model But given a point source model, of luminosity L_1, we can always derive another of the same mass and of arbitrarily smaller luminosity L_2 If we simply reduce the strength of the internal point-source, the star can only contract on itself, and hence as above find a new configuration of equilibrium Counting up of arbitrary constants in the fundamental differential equation for a point source model shows that the model (for given mass and luminosity) has in fact an additional degree of freedom, after arbitrarily choosing L (less than some upper limit) and the mass M, we can arbitrarily fix the radius, that is, arbitrarily fix the effective temperature (I owe this to discussions with Mr T G Cowling) Thus we can find point source models of given effective temperatures and *any* luminosity

Again, take any one model, of luminosity L and mass M, with any particular source distribution Arbitrarily diminish the intensity of the sources The star can only contract It contracts either slightly or catastrophically In the latter case the original model is unstable, but it must sooner or later arrive at a new equilibrium configuration In either case we arrive at a state of arbitrarily smaller luminosity and the same mass, and this altered state will possess some definite source distribution to correspond

In Eddington's method of approach the energy-sources may be considered as a population of taps, of given relative concentration towards the centre, but capable of being turned on to any amount that may be required It is then shown that the concentration by itself alone determines the amount they would have to be turned on for a steady state But we have no guarantee that in the model thus constructed the physical conditions of the material at each neighbourhood will be in fact such as to turn them on to the required amount For example, the surviving degree of adjustment by means of temperature alone leads, as we have seen, to a contradiction with observation In the uranium type of problem, with absolute rate of generation, we cannot *begin* with a given population-concentration, we have to find it—to find the concentration gradient of the solution of uranium in calcium from centre to boundary necessary for a steady state

By considering an unrestricted range of relative *density* distributions consistent with a *given* luminosity and a given mass, I have shown in *Mon Not R A S*, Nov 1929, that the solution of the uranium problem by equilibrium considerations only is not unique, there are an infinite number of different relative density distributions possible, all compatible with a given L and M, specified by a certain function ϕ The observed effective temperatures occurring in Nature restrict the forms of the ϕ's to those possessing a certain property described by giving a definite numerical value to a dependent quantity C The question is, What are the physical considerations restricting ϕ?

I need scarcely say that, while advancing these more elastic theories, I am deeply sensible of the services which Prof Eddington's investigations have rendered to the study of stellar structure

The Growing Importance of Frequency

The relation between energy and mass, $e = mc^2$, where c is numerically the velocity of light, indicates that energy has mass and that mass has energy, furthermore, it suggests that the conservation of mass of the chemists *is* at *one* with the *conservation* of energy of the physicists This relation appears more emphatic if we so alter the unit, either of mass or of energy, that the constant c^2 becomes superfluous, and we write in consequence $E = M$ This would be correct, for example, if our new unit of energy were 9×10^{20} ergs We do not therefore state that energy is necessarily matter, but we do state that the same abstract number will express matter in terms of energy, or energy in terms of mass We must always be careful not to confuse, say, sheep and oxen, because we happen to see the same number of these different animals

It is remarkable that transfers of energy take place in quanta of value hf, where f is frequency and h is Planck's constant We can again alter our unit of energy, or our unit of time, in such a manner that h is superfluous, and the relation $e = hf$ becomes $E = F$, and this indicates that energy and frequency can be expressed by the same abstract number, so that a *conservation of energy has its counterpart in a conservation of frequency* Thus in place of the linkages of Nature, to which we are growing accustomed, such as

$$e = mc^2 = hf = Jq,$$

we can, by adopting what I venture to call super-units, write down

$$E = M = F = Q,$$

wherein energy, mass, frequency, and heat appear all expressed with the same abstract number We are not unfamiliar with this Energy is expressed sometimes in ergs, at other times in equivalent calories, or even in volt-electrons

It is the purpose of this note to urge a status for frequency comparable with that of its older brethren, if, indeed, we are not recalling the music of the spheres to a fresh harmony

Again, the Einstein Bohr equation

$$h\nu = W_1 - W_2$$

can be written

$$h\nu = hf_1 - hf_2,$$

or more simply

$$\nu = f_1 - f_2,$$

which expresses clearly the beat or heterodyne character of the observable frequency ν derived from two unobserved or unobservable frequencies f_1, f_2 characteristic of the atom, due to the necessity of standing waves or 'repeat patterns' of the electronic waves in their passage around the nucleus

So, too, the Einstein transformation equation

$$T = (t - vx/c^2)/\sqrt{1 - v^2/c^2}$$

may refer to a particle moving with velocity v relatively to an observer Now this equation, as de Broglie pointed out, involves another velocity u, which may be denoted by c^2/v and is greater than the velocity of light

It may be thought of as a phase velocity, of which v may be shown to be the group velocity In the case of a mass m, moving with velocity v, if we state

$$h\nu = mc^2$$

$$c^2 = uv$$

$$u = \lambda\nu$$

and multiply the left sides together, and the right sides, and equate, we have after cancelling

$$\lambda = h/mv$$

This is the precise relation which Davisson and Germer, and G P Thomson, have shown to hold for an electron Thus the frequencies of waves seem to be achieving a remarkably fundamental rôle, comparable with that of energy Waves of what? The key to the central tower of physics has yet to be found No less obscure is the connexion between the two different types of electric charge and their attendant waves The linkage between energy and time, which resembles that between p and q in Dirac's equations, also suggests a close relationship between energy and frequency

A Cosmological Conjecture

According to quantum mechanics, a harmonic oscillator of frequency ν has a lowest energy state the energy of which is $\frac{1}{2}h\nu$ When the electromagnetic field is treated, after Rayleigh and Jeans, and Debye, as an assemblage of independent harmonic oscillators, one of which is associated with each of the normal modes of vibration of the ether, this leads to the result that there is present in all space an infinite positive energy density It is infinite because there is supposed to be no upper limit to the frequencies of possible normal modes

According to Dirac's theory of the proton (*Proc Roy Soc*, A, January 1930) there is an infinite negative energy density associated with an infinite number per unit volume of relativistic electrons in negative energy states Moreover, since the electrons are handled as a wave phenomenon, for great negative energies the number of states in unit energy range presumably is the same function of the energy as the number of normal modes for the ether is of the frequency

It is, therefore, a natural conjecture to suppose that these two infinite energy densities just cancel each other If they do, it indicates a certain artificiality in our present theories and points to the possibility that radiation and the electromagnetic field may be assimilated into a unified theory which regards them, like the protons, as another aspect of the negative energy electrons In such a theory, these two infinite energy densities would be balanced off at the outset and so would never appear

We refrain from calling our conjecture a theory in deference to the views of Prof H E Armstrong recently expressed in these columns

Unimolecular Films

The changes of state occurring in unimolecular films were the subject of a recent investigation (Lyons and Rideal, *Proc Roy Soc*, **124**, A, 322, 1929) It was concluded, following Muller (*Proc Roy Soc*, **114**, A, 542, 1927), that the molecules in the film were generally tilted The suggestion was made that in the solid films of long chain substances the tilt of the molecules and therefore their areas were determined by the interlocking of zigzag chains Since these views have recently been criticised (Adam, *Proc Roy Soc*, **126**, A, 526, 1930), owing partly to a misunderstanding, a recapitulation of them and the evidence in their favour seems desirable

The hypothesis of interlocking chains applies to *solid* films These may be considered as consisting of unimolecular 'crystalline' sheets The hypothesis requires that long chain substances with small asymmetric polar head groups should give such films (where the chains have lost their flexibility) with one of two limiting areas, namely, 20 6 sq A and 26 2 sq A per molecule Clearly, substances with bulky substituents in the chain and those containing the large disc like aromatic nucleus cannot be used to test this suggestion

The smaller area is given by a very large number of compounds, but the larger area, as is to be anticipated, is only obtained in a few instances, and its validity has been questioned on both the experimental and theoretical sides

The results of Adam and ourselves on the amines and their hydrochlorides show that the films of these materials are more complex than was suspected previously A more detailed investigation is now being made, the results of which will be published on completion of the work However, it may be stated that the solid films of heptadecylamine have been obtained both with areas of 20 6 sq A per molecule and 26 2 sq A depending on the conditions The amine hydrochlorides (with which most of Adam's work was carried out) have yielded as yet only areas of 20 5 sq A per molecule in agreement with his values The variations in area seem to be due to a fundamental property of the system and may possibly be due to a dimorphism as for the ureas (v inf) The X ray data on amine hydrochlorides (Bragg, Solvay Congress Rep, 1925, 36) show corresponding anomalies which were also attributed to polymorphism

The criticism on the theoretical side was chiefly concerned with the properties of the ureas

The long chain ureas give an area of 26 2 sq A per molecule below a certain temperature, above which they give 20 5 sq A It was suggested that the sharpness of the transition, which occurs over a very narrow temperature range, is inconsistent with the hypothesis of interlocking chains We consider that this sharpness is to be expected, for probably the change is due to a true transition between two distinct crystalline states This is an example of

dimorphism in two dimensions which is comparable with that of rhombic and monoclinic sulphur in three dimensions

The increase of chain length affects the transition temperature in a similar manner to its effect on many other physical properties

The existence of solid films with areas of 26 2 sq A per molecule does, therefore, support the hypo thesis of interlocking chains

A further criticism has been brought that some films which have areas corresponding with the interlocking position may not be solid There is, however, no sensitive process for distinguishing between a viscous liquid and a weak solid film The ordinary method of blowing dust particles on the surface may give very doubtful results in border-line cases, since the pressures generated by blowing, although apparently small, may have a profound influence on a thin unimolecular film The monoglyceride films of area 26 2 sq A per molecule for which "dust on the surface obviously does not move very easily" (Adam, *Proc Roy Soc*, **117**, A, 532, 1928) are examples of such border line cases Here a more delicate technique is needed to establish their physical state without ambiguity

Nevertheless, it is clear that films with an area per molecule slightly larger than that calculated for interlocking may be liquid These films are very likely to be obtained when the angle of free tilt is close to the interlocking angle The liquid alcohols fulfil these requirements, and the available evidence suggests that the area per molecule is slightly greater than that found for fatty acids (Adam and Dyer, *Proc Roy Soc*, **106**, A, 694, 1924)

Further misconception has arisen from the bearing of this hypothesis on the results of X ray analyses of crystals of long chain compounds Interlocking should give rise to one of a series of calculable tilts The principle seems to apply there, at least to a first approximation It must, however, be remembered that the crystal is of a much more complicated structure, and disturbing influences are much more likely there than in a thin film (cf Muller, *Proc Roy Soc*, **124**, A, 317, 1929, on the mutual influence of the polar groups of the molecules forming the bimolecular layers of the crystal)

In conclusion, it may be stated that all the ali phatic compounds yet examined by X ray methods consist of plane zigzag chains The areas of films calculated for the interlocking positions do not depend on one analysis alone, but are based on the collected results for these different substances, and in particular on the accurate and detailed analysis of stearic acid and the hydrocarbons (Muller, *Proc Roy Soc*, **114**, A, 542, 1927, **120**, A, 437, 1928) which are in such excellent agreement

Structure of Naphthalene and Anthracene

IN a paper published in the *Proceedings of the Royal Society* (vol A, 125, p 542, 1929) on the structure of naphthalene and anthracene, J M Robertson comes to the conclusion that "the scattering centres lie nearer the *ac* planes than the *bc* planes, but no simple structure with a plane of symmetry parallel to the *ac* plane is possible", and that the scattering centres lie along a chain structure similar to hydro carbons On the other hand, the structure of hexa methylbenzene as determined by K Lonsdale (*Proc Roy. Soc.*, vol. 123, p 537, 1929) suggests that the benzene rings in aromatic compounds should in all probability be plane structure This has further support from the plane hexagonal structure of graphite (Ott, *Ann d Phys*, vol 85, p 81, 1928) As regards whether the scattering centres are nearer the *ac* plane or the *bc* plane, the optical and magnetic anisotropies which have been measured by S Bhaga vantam (*Proc Roy Soc*, vol A, 124, p 545, 1929) require that the carbon atoms should lie nearer the *bc* plane than the *ac* plane The structure proposed by Robertson, however, does not explain the in tensities of reflection from many of the crystal planes, which he supposes are due to small glancing angles for those particular reflections But on evaluating the angle factors for the intensities it is seen that such large discrepancies cannot be explained in that manner

I made an X ray investigation into the structure of naphthalene and anthracene, the results of which will be published shortly It has been found that the best agreement for the intensities of reflections from these crystals is obtained when all the carbon atoms in one molecule are supposed to be in one plane and the planes of the molecules are inclined to the cell faces The correct positions of the molecules are obtained by first placing them along the *bc* planes, then rotating them through 25° about the *c* axis (the two molecules in the unit cell being rotated in opposite directions), and then rotating them about *b* axes through 12° and 9° for naphthalene and anthra cene respectively The agreement will be best seen by referring to the table appended herewith, where the results for some simple planes are given Similar agreements were obtained for all the forty planes from which reflections were observed It can be easily seen that agreements are much better than those obtained by Robertson

TABLE I

Indices	Naphthalene		Anthracene	
	Theoretical Structure Factor	Experimental Structure Factor	Theoretical Structure Factor	Experimental Structure Factor
001	15 3	15 3	13 2	13 2
002	6 0	6 2	8 8	8 4
110	18 2	17 5	27 0	30 3
11$\bar{1}$	5 1	5 9	10 2	8 9
020	6 6	7 0	8 3	7 5
200	15 0	14 8	19 8	18 3
20$\bar{1}$	24 8	23 0	21 0	14 9
20$\bar{2}$	5 2	4 8	9 2	9 9
210	10 0	10 6	14 7	16 2
21$\bar{1}$	9 2	10 0	12 6	14 9

The intensities of 007, 20$\bar{7}$, 40$\bar{7}$, 607 reflections from naphthalene and 00$\bar{9}$, 209, 40$\bar{9}$, 609 reflections from anthracene, on which Robertson bases his arguments for supposing that the scattering centres lie nearer the *ac* planes, agree qualitatively with experiment as the structure factors for the 407 and 40$\bar{9}$ planes respectively come out the highest among the series according to this arrangement of placing the carbon atoms

KEDAVESWAR BANERJEE
210 Bowbazar Street,
Calcutta, Nov 26, 1929

I BELIEVE Dr Banerjee's structure to be essentially correct It has been clear to me for some time that the last two sections of my paper to which Dr Banerjee refers must be amended as regards the distribution of the scattering centres in the *a* and *b* directions During last summer, Sir William Bragg made 'abso

lute' measurements of the intensities of the reflections from a number of anthracene planes These measurements were expressed as ratios between the structure factors actually found, and the structure factor to be expected if all the atoms were in the reflecting planes It was intended that these results and deductions therefrom should be incorporated with my paper, the publication of which was to be delayed for the purpose unfortunately, owing to my absence from England, there was some confusion during the revision of the proofs and this was not done Sir William Bragg's figures lead to a structure resembling Dr Banerjee's so closely that it is interesting to give the following quotation from a letter which he wrote to me It is in the form of notes upon a table of structure factors

No 1 "A flat molecule, axis along the *c* axis, plane of molecule making an angle of 25° with the *bc* plane This gives good values in the *c* zone, but not in the *b* zone, especially the $20\bar{1}$ is far too weak So next (No 2) the molecule is tipped over a little more to the upright position (about 6°) This greatly improves the *b* zone In No 3 a slight buckle is put in, to try to improve the notable 204 The consequences are not very striking On the whole there is so much agreement that we cannot be very far wrong"

Plane	S Observed	S Calculated		
		No 1	No 2	No 3
200	0 70	0 68	0 58	0 60
020	0 33	0 32	0 32	0 31
110	0 50	0 47	0 48	0 47
210	0 67	0 58	0 52	0 55
310	0 20	0 23	0 19	0 17
410	0 55	0 67	0 39	0 29
320	0 50	0 55	0 40	0 42
001	0 22			0 23
002	0 26		0 19	0 15
$20\bar{1}$	0 50	0 14	0 43	0 40
204	0 80	0 27	0 50	0 73

Whether the carbon atoms in these molecules lie in one plane as strictly as do the graphite carbon atoms, or those of hexamethylbenzene, can scarcely yet be stated with certainty But the structure certainly appears to approximate to those types

The Crystal Structure of Xenon

Of the rare gases, argon is the only one of which the crystal structure is known (F Simon and V Simson, *Zeit f Phys*, **25**, 160, 1924) We have now been able to determine the crystal structure of xenon by a method allowing the use of a very small quantity of gas it was condensed as a very thin layer upon the surface of a quartz capillary internally cooled by liquid air The thickness of the condensed layer can be estimated to be about 0 004 cm

We obtained very good photograms by the powder method, using a Philips tube fitted with iron anticathode in less than 2½ hours exposure From the photograms, consisting of sixteen lines, three of which correspond to the $K\beta$ radiation of iron, we have been able to establish that xenon, like argon, shows a face centred cubic structure

The lattice constant of the elementary cell, consisting of four atoms, is $a = 6\ 18 \pm 0\ 01$ A the volume is $236\ 03 \times 10^{-24}$ c c and the calculated density, taking as the weight of the hydrogen atom $1\ 65 \times 10^{-24}$ gm, is $d = 3\ 64$ gm /c c (The density of liquid xenon at the boiling point is 3 06 (Ramsay and Travers)) From the previous data the atomic radius of xenon can be calculated as 2 18 A The atomic radius calculated from gaseous viscosity measurements (A G Nasini and C Rossi, *Gazzetta*, **58**, 433, 1928) is 1 70 A, thus being smaller than the crystal structure datum we may point out, however, that the two figures bear the same ratio as for argon The radius calculated from the present measurements is very similar to those, calculated by Goldschmidt, of the positive ions monovalent iodine, divalent tellurium, and tetravalent tin, having the same number of external electrons (Geoch Verteilungsgesetz d Elem, *Norske Vidensk Akad*, Oslo, **7**, 54, 1926)

We are now examining the crystal structure of krypton, but a modification of the present apparatus will be necessary, since the vapour pressure of krypton, at the temperature reached as above, is somewhat too high A more detailed account of the present research and of the work on krypton will appear elsewhere

Behaviour of Electrons in a Gas Tube

The late Mr Campbell Swinton observed (*Proc Roy Soc*, **61**, 79 1897) that a carbon anticathode in a gas X ray tube under certain conditions showed a ring of fluorescence which he considered due to the hollow nature of the cathode stream The following preliminary account of some experiments with a gas X ray tube of the Shearer type shows that the effect can be more complex than is usually suspected

The anticathode end of a Shearer tube was replaced by a brass tube of approximately the same length and

Fig 1

diameter The tube was waxed in the usual way to the glass cylinder of the X ray tube and was sealed at the other end by a glass plate so that the luminescence due to the electron stream from the cathode could be viewed end on

It is found that the glass fluoresces in a very striking manner At a pressure just greater than that at which the tube would normally be worked when producing X rays, two bright concentric rings appear The outer one is rather diffuse, the inner is remarkably sharp As the pressure is decreased the inner ring subdivides into others equally well defined, and later, a bright point of fluorescence appears at the centre of the rings accompanied by intense local heating of the glass and the production of X rays The tension applied to the tube was of the order of 10,000 volts, and the effect observed was the same whether the

current was alternating or rectified An increase in voltage seems merely to intensify the rings and to result in their further subdivision That the rings are caused by electrons is shown by the fact that they can be moved by a magnet That they do not occur at different moments of a single discharge cycle can be shown by viewing them in a rotating mirror

The accompanying photograph (Fig 1) was taken at an angle of about 45° to the glass plate so as to avoid the general illumination inside the tube and clearly illustrates the multiple ring formation

The Diffraction of X-Rays by Vitreous Solids and its Bearing on their Constitution

The diffraction of X rays by glasses has been the subject of many investigations during the last fifteen years, notably by Scherrer, Wyckoff, and Seljakow Scherrer obtained broad diffraction bands similar to those obtained with liquids, whilst Wyckoff obtained, in general, more complicated patterns consisting of lines, bands, or lines superimposed on bands The latest contributors to this subject are Parmelee, Clark, and Badger (*Jour Soc Glass Technology*, 13, 285, 1929), and Clark and Amberg (*ibid*, p 290), who have also obtained broad diffraction bands for silica and felspar glasses Quite apart from the validity of any of these measurements, no previous workers appear definitely to have identified the diffraction bands with small crystallites in the glass

With the view of obtaining more precise data on the constitution of glasses we have recently examined the diffraction effects produced by passing copper $K\alpha$ radiation through silica, wollastonite, sodium borate, potassium borate, boric oxide, selenium, potash and soda felspars, glucose and sucrose, in the glassy state Results have also been obtained with the more usual soda-lime-silica and boro silicate glasses

We have been able to show that silica glass corresponds to either cristobalite or tridymite crystallites, of average size 1 5 2 0 × 10^{-7} cm, with the evidence very much in favour of cristobalite Also we have shown that wollastonite ($CaSiO_3$) glass corresponds to the crystalline pseudo wollastonite and that sodium borate $Na_2B_4O_7$ corresponds to crystals of this substance

In the case of potash felspar (K_2O Al_2O_3 $6SiO_2$), it has been found that the crystallites of the glass are mainly silica (probably cristobalite) The identity of the remainder is as yet uncertain Boro silicate glass containing 70 per cent SiO_2, 17 per cent B_2O_3, and other substances in minor proportions gives a very similar band It has been found, in further confirmation of the observations, that potash felspar glass devitrifies to cristobalite and that wollastonite glass, which, it is to be expected, is much more stable, devitrifies to crystalline wollastonite at 900° C

We are not in agreement with the observations of Parmelee, Clark, and co workers on the positions and number of bands obtained with fused silica and with felspar glass We obtained for fused silica one band with a spacing of 4 33 A, whereas they obtained two bands, one at 7 1 A, and a faint one at 2 5 A Our work was carried out with copper $K\alpha$ radiation, whereas they worked with the radiation from a molybdenum target We have repeated our measurements with molybdenum $K\alpha$ radiation, and again obtain the strong band at 4 33 A, together with a faint and much more diffuse band at about 1 5 A For equal distances of specimen from film the breadth of a band when using copper $K\alpha$ is roughly twice that with molybdenum $K\alpha$, so that failure to detect the faint band with copper $K\alpha$ may have been due to this cause We have tested out this point and have failed to obtain the second band using copper $K\alpha$ radiation with the distance from specimen to film reduced by more than half It seems probable, therefore, that the faint band obtained with molybdenum $K\alpha$ radiation is spurious and that the only one on which reliance can be placed is that at 4 33 A We have checked this spacing with those of standard substances obtained on the same apparatus and are unable to understand the value of 7 1 A given by Parmelee and Clark We hope shortly to publish these results elsewhere in greater detail

Scattering of Electrons and α-Particles.

Experiments by Rutherford show anomalies in the scattering of α particles in a certain range of velocities for light elements Similarly, the scattering of electrons by atoms shows anomalies for small velocities, as was discovered by Ramsauer Both effects can be treated in a similar way by wave-mechanics considerations

Let us first consider the corresponding one dimensional problem A particle is reflected (scattered) from a potential valley When the valley has the simple form of a rectangle, the effect can be treated as the well known phenomenon of interference from thin plates in optics For certain velocities (frequencies) no particles (light) are reflected, for other velocities the coefficient of reflection has a maximum This is not limited to a rectangular shape but occurs for very general potential valleys

In the three dimensional case, particles which are treated as a plane wave are scattered by an atom or by a nucleus, which is assumed to possess spherical symmetry This plane wave may be enveloped into a series of spherical harmonics [1] For each component one obtains a scattering coefficient, which is an oscillating function of the velocity of the incident particles

In the first approximation the atom can be considered as a potential valley, which can be determined by the methods of Hartree A nucleus should also be treated in this approximation as a potential valley, as was pointed out by Gamow in his theory of radio active disintegration

For electrons of sufficiently small velocities, only the zero order scattering is appreciable The minimum of the zero order scattering explains the Ramsauer effect [2] Something similar is true when an α particle hits a nucleus with a velocity which is high enough so that it passes over the potential wall separating the inside of the nucleus from the outer space For certain velocities of the incident particles the scattering coefficients of low order are affected a great deal by the presence of the potential valley. The resulting modification of the Rutherford scattering law has been calculated and reproduces the general type of experimental curves Quantitative agreement cannot be expected until the shape of the potential valley of the nucleus is known in detail

The detailed presentation will be given in an article to appear in the *Zeitschrift für Physik*

Scattering of α-Particles by Light Atoms

In a letter to Nature of Feb 1, and in greater detail in the *Philosophical Magazine*, vol 9, No 56, February 1930, Prof A C Banerji has discussed some wave mechanical calculations on the scattering of α particles by light atoms I should like to make some remarks on this problem, which I have treated in a paper to appear in the *Zeitschrift für Physik*

The first remark refers to the choice of nuclear model While Prof Banerji has assumed a central field of force consisting of a repulsion proportional to the inverse cube of the distance to be added to the Coulomb field due to the nuclear charge, I have taken a model corresponding to that used by Gamow to explain the radioactive decay, that is, for distances r larger than the 'radius' r_0 of the nucleus, the potential is supposed to be Coulombian and for $r<r_0$ a constant V_0 The scattering calculated by the mathematical method due to Born shows all the characteristic deviations from the normal Rutherford scattering, which have been traced experimentally by Bieler, Rutherford, and Chadwick

We cannot expect that this very rough model should give quantitatively right results, but if we determine r_0 and V_0 so as to give the experimentally measured scattering for small angles, we obtain a first rough approximation to the potential in the nucleus For aluminium we get for r_0 the value 2 23 × 10^{-13} cm, and for magnesium a somewhat smaller value, in agreement with the general increase of nuclear dimensions with atomic number In contrast with this, Prof Banerji, who also defines a 'radius' r_0, gets a larger value for magnesium than for aluminium Besides, there is the difference that our r_0 does not depend on the velocity of the incident α-particle

The above mentioned scattering formulæ contains the velocity v of the α particle and the scattering angle θ only in the connexion $v \sin \theta/2$, therefore if v and θ are varied so that $v \sin \theta/2$ is constant, the scattering will remain the same This gives a very simple displacement rule which allows us to calculate the scattering for every v and θ if the scattering is known for one value of v and all values of θ, or for one value of θ and all values of v

It can be shown that this displacement rule, which seems to be in good agreement with experiments, holds for every nuclear potential of central symmetry if we confine ourselves to the first approximation of the Born method That this is legitimate is not quite obvious, since the first approximation is not everywhere small compared with the zero approximation For $r=0$ the two approximations are, for example, of the same order of magnitude Also Prof Banerji confines himself to the first approximation of the Born method, and for his potential this approximation is even infinite in the origin

The next problem is how to improve the very rough assumptions about the potential within the nucleus For this purpose I have considered the following unclear model Let r_0, r_1, r_2, r_n be a sequence of numbers so that $r_p>r_{p+1}$ ($p=0$, 1, 2, n) For $r>r_0$ the potential is again supposed to be Coulombian Inside the shell $r_p>r>r_{p+1}$ it is supposed to have the constant value $V_p(p=0, 1, n)$ The Born method gives again a very simple expression for the scattering by this model This expression contains the constants r_0, r_1, r_n and V_0, V_1, V_n From the experimental scattering curves it will be easy to determine the constants V_p when the r_p's are arbitrarily given, that is, we have a general method from the experimental data to determine the potential in the nucleus with any desired accuracy The performance of this work demands, however, more accurate measurements than are yet at hand

It should also be remarked that according to our formulæ the sensitivity of such determination of the nuclear potential will decrease for decreasing distances from the centre Indeed, the influence of a change of the potential on the scattering result will vanish for distances very small compared with the de Broglie wave length of the incident α particle

Added in Proof—In the issue of *Die Naturwissenschaften* of Mar 14, Mr Th Sexl has treated the problem of the scattering of α particles from a point of view similar to that of Prof Banerji In addition, he has also considered the case of an attractive force, which varies with the inverse fourth and fifth power of the distance The last case corresponds with the idea proposed by Debye and Hardmeier, that the anomalous scattering should be sought in the polarisation of the nucleus produced by the α particle As the agreement with the experimental results in none of the cases investigated by him is quite satisfactory, Mr Sexl infers that a nuclear polarisation is insufficient to explain the results, and that some other effect must be looked for

Electron Affinities of the Elements

The various attempts to find experimentally the electron affinities of the chemical elements have met so far with little success Since such a determination would probably help in shedding light on chemical reactions and the formation of molecules, it is obviously important Accordingly, a method is here outlined which enables one to say approximately which elements have a positive electron affinity, and also to predict the approximate position of whatever lines of the electron affinity spectrum occur

By definition, the electron affinity of an atom is the ionisation potential of its negative ion, or the difference in energy between the normal state of the atom and the normal state of the ion From the work of Bowen and Millikan and others on stripped atoms, many of the higher ionisation potentials are known In the iso electronic sequence Be^{++}, Li^{+}, He, H^{-}, the ionisation potentials of the first three are known, and so we may extrapolate to get that of the fourth This would be our method of estimating the electron affinity of the hydrogen atom In this case, one must make a long extrapolation (from 24 47 volts), and so the attainable accuracy is not extremely high Assuming that the square root of the ionisation potential is linear in Z, the atomic number which gives reasonable agreement with the experimental values, one finds the electron affinity of H to be 1 4 volts Other methods of extrapolation may yield somewhat lower values This is in agreement with theoretical work of Bethe (*Zeits f Phys*, 57, 815, 1929), who concluded that the electron affinity was greater than 0 75 volts

If we examine the first row of the periodic table, then it seems almost necessarily to follow from any reasonable extrapolation that the electron affinity will show the following behaviour For helium, it will be negative, indicating that He^{-} is not stable For lithium, it will be greater, perhaps positive, to decrease again with beryllium, increasing to carbon, decreasing to nitrogen, and increasing to fluorine, where the value is about 3 5 volts The second row shows a similar behaviour, the increases in both cases being linear

The first excited states of H^{-}, 2^1S and 2^3S, lie close below the normal state of H, and the states 2^1P and 2^3P both lie above, tending to show that no discrete

electron affinity spectrum for H^- is possible, as Bethe also concluded The data used in the extrapolation are taken from the International Critical Tables, vol 5, and from B Edlén and A Ericson (NATURE, **124**, 683, 1929)

If we consider the iso-electronic sequence Ca^{++}, K^+, A, Cl^-, using data from I S Bowen (*Phys Rev*, **31**, 457, 1919) and from K W Meissner (*Zeits f Phys*, **40**, 839, 1929), then assuming the second differences to be approximately constant, one obtains 3 volts for the electron affinity of chlorine, but the first excited state of Cl^- lies above the normal state of the chlorine atom, so one would likewise expect no discrete electron affinity spectrum here

A systematic investigation may possibly reveal elements which possess such a spectrum The present note merely purposes to direct attention to a method which may perhaps be used with profit in the search for whatever lines may exist Even the rough extrapolation used here would probably be helpful in estimating the position of 'polar' states of atoms at infinite separation, which information one needs in applying the Heitler and London method, as extended by Slater, to find the electronic energies of a diatomic molecule

Cambridge, Feb 6

Energy Losses of Electrons in Mercury Vapour

A STUDY has recently been made by me of the effects of collisions with mercury atoms of electrons of energies of 8 volts, 18 4 volts, 34 6 volts, and 49 volts The collisions of the electrons and mercury atoms took place in a field free space from which those scattered at a definite angle passed into an analysing chamber

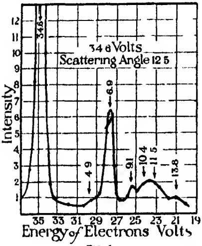

FIG 1

from which the mercury vapour had been removed Here a velocity analysis was made by an electrostatic method instead of by the usual magnetic field The paths of the electrons were bent by an electric field between two curved molybdenum plates While the experiment was in progress, a paper appeared by G P Harnwell (*Phys Rev*, vol **33**, p 559) in which the same method of analysis was used Apparently, however, it failed to give results with electrons of energies less than about 40 volts and the resolution was somewhat low Just recently, results of a similar experiment on energy losses in mercury have been published by Whitney (*Phys Rev*, vol **34**, p 923), in which a magnetic analysis was used giving about the same resolving power as the method used by me

The accompanying curves (Figs 1 and 2) show typical curves The main peak represents electrons which have suffered elastic collisions, the others electrons having lost various amounts of energy by inelastic collisions Most peaks could be measured with an error of not more than 0 2 volt

The inelastic peaks may be identified as follows

(1) An energy loss of about 4 9 volts This peak probably includes the 4 7 volt, 4 9 volt, and 5 4 volt energy levels, corresponding to the 1^3P_0, 1^3P_1, and

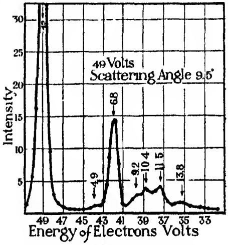

FIG 2

the 1^3P_2 levels The resolving power was not sufficient to separate the 4 7 volt and 4 9 volt levels, and the 5 4 volt peak is too close to the 6 7 volt peak

(2) An energy loss of 6 7 volts, the 1^1P_1 energy level This peak is several times as intense as any other at all voltages studied except at 8 volts, where the 4 9 volt peak appeared a little more prominent

(3) An energy loss of about 9 2 volts This probably corresponds to some of the many energy levels near ionisation

(4) An energy loss of 10 4 volts This corresponds to ionisation of the mercury atom

(5) An energy loss of 11 5 volts This may be the result of two successive collisions, one losing 4 7 volts or 4 9 volts, and the other 6 7 volts (See below)

(6) Another peak occurs at 13 5 to 14 volts It is not sharp enough to be located accurately It probably represents two collisions, each resulting in the loss of 6 7 volts

The first two peaks were also found to occur with about the same relative intensity by Whitney He worked at sixteen different voltages between 5 and 41 He found a peak at 9 7 volts which probably corresponds to mine at 9 2 He suggests it may be due to two successive collisions of 4 9 volts loss each He also gets a peak at 11 7 volts which without doubt corresponds to mine at 11 5 The exact position of this peak is a little uncertain in both experiments In his experiments it seemed to be mixed up and inseparable from the ionisation peak No doubt this is due to the fact that he worked at a pressure corresponding to a temperature of 94° C, while in my experiments the pressure was that corresponding to about 25° C

The intensity of the 6 7 volt peak is very striking The corresponding spectral line (λ1849) is very difficult to observe as it is so far in the ultra-violet These experiments when carried further should prove

valuable in estimating the relative probability of excitation to the various levels which are difficult to observe spectroscopically I think sufficient resolving power could be obtained to separate the 4 7 volts and 4 9 volt levels The method has the great advantage that the collisions take place in a completely field free space

The intensity of the 11 5 volt peak is surprising If it is the result of two successive collisions as explained above, it should be less intense than the 4 7 volt, 4 9 volt, and 5 4 volt peak No satisfactory explanation of its intensity has been found Foard, in an abstract (*Bull Am Phys Soc*, Dec 13, 1929), has described some similar experiments using a magnetic analysis He seems to have obtained slightly higher resolution He finds a peak at 7 7 volts, the 1^3S_1 energy level This peak does not occur either in my experiments or in those of Whitney Otherwise the same peaks were found

In the present experiment, the electron gun could be rotated to give an angular distribution of the scattered electrons and some results have been obtained They are not very accurate, and agree in general with those of Arnot (*Proc Roy Soc*, vol 125, p 660), so nothing further need be said about them

These experiments were made possible by the kindness of Prof A M Tyndall in placing the facilities of the Wills Physical Laboratory at the University of Bristol at my disposal The work was done while I held an 1851 Exhibition Senior Studentship

Glancing Angle of Reflection from Calcite for Silver ($K\alpha_1$) X-Rays

We have measured the first order glancing angle at which the $K\alpha_1$ line of silver is reflected from the cleavage planes of calcite by a method independent of any used by those who have obtained the most reliable results so far The weighted mean value of fourteen independent observations reduced to 18° C is 5° 17′ 13 81″ ± 0 06″

This value was obtained from spectrograms taken on a new spectrometer specially designed to utilise the displacement method introduced by H S Uhler (*Phys Rev* [11], 11, 1 20, 1918) A full description of the method, instrument, and results will be given later

The value of the wave length corresponding to the above glancing angle is 0 558238 A ± 0 000002 A obtained by using 3 02904 A for the 'effective' grating space of calcite (Siegbahn, "Spectroscopy of X Rays", 1924 edition)

The thermal coefficient of expansion at 18° C for the grating space of calcite obtained from the most trustworthy sources, without approximations, is $0\ 0000102_2/°$ C This value differs by about 2 per cent from the generally quoted value originally given by W Stenström (Dissertation, Lund, 1919) as a sufficient approximation

It is interesting to note that our value of the glancing angle is 1 4″ smaller than that given by G Kellström (*Zeit f Phys*, 41, 516, 1927) for the first order of calcite, namely, 5° 17′ 15 2″ The probable error of the unweighted mean of Kellström's seven determinations for this order is $\pm 0\ 04_5''$ The unweighted mean of his four second order determinations is also larger than ours and has relatively four times this probable error With such a difference existing, one wonders if the grating spaces of the crystal specimens used were the same We employed an unusually selective piece of calcite which was cleaved from an excellent specimen of Iceland spar contained in the Marsh collection of Yale University

Our value is larger than those of K Lang (*Ann d Physik*, 75, 489, 1924), A Leide (Dissertation, Lund, 1925), and A P Weber (*Zeit f Wiss Photo*, 23, 149, 1925), although coming within 0 11″ of Lang's and 0 36″ of Leide's results when their probable errors are added to their respective mean values

The Nuclear Moment of Lithium

The fact that the hyperfine structures of spectral lines are so much narrower than the multiplets in the same spectrum is due principally to the fact that the latter are produced by the magnetic moment of the electrons, while the former originate from the magnetic moment of the nucleus, which is usually attributed to nuclear protons, and is, therefore, about 1840 times smaller

The hyperfine structure of the Li^+ spectrum, discovered by Schuler (*Zeit f Phys*, 42, 487, 1927) is of the same order of magnitude, however, as the multiplet separations themselves From this fact Heisenberg (*Zeit f Phys*, 39, 516, 1926) drew the conclusion that the magnetic moment of the lithium nucleus was of the same order of magnitude as that of an electron, and therefore caused by electrons in the nucleus and not by protons The experiments of Taylor (*Zeit f Phys*, 52, 846, 1929) on the Stern Gerlach effect with lithium atoms failed, however to indicate the expected large magnetic moment for the nucleus

In the following we will show that the nuclear magnetic moment is not very large, and that the wide hyperfine structure is caused by the presence of a single 1*s* electron in the configurations considered

In a recent letter to Nature (125, 16, 1930), Fermi has given an expression for the interaction between the nuclear moment and the external electrons derived from quantum mechanics [1] For an *s* state in an hydrogenic atom the doublet separation (*s* states have $j = 1/2$ and thus split into two levels) will be

$$\Delta\nu = \frac{8}{3} R\alpha^2 \frac{Z^3}{n^3} \frac{g(i)}{1840} (i + \tfrac{1}{2})$$

In this expression we denote by $g(i)$ the ratio between the magnetic and mechanical moments of the nucleus, its Landé g value, but in units 1840 times smaller than used for electrons, in order to obtain the magnetic moment of a spinning proton as unity Since the mechanical moment of a spinning proton is 1/2 quantum unit, its $g(i)$ is thus 2 The mechanical moment of the nucleus is denoted by i

Applied to doubly ionised lithium the lowest *s* state would have a doublet separation of

$$\Delta\nu = 0\ 228\ g(i) \ (i + \tfrac{1}{2}) \text{ cm}^{-1}$$

For the 1*s* 2*s* and 1*s* 2*p* configurations of Li^+ we may assume that the hyperfine structure is mainly due to the presence of the 1*s* electron The added electron will have some screening effect on the 1*s* electron, but as it is an outer electron this effect will be very small Furthermore, the screening effect of the 1*s* electron upon the 2*s* or 2*p* electron will be large, and as these

[1] The same expressions were known to us before from unpublished material of H Casimir presented at a meeting in Copenhagen last April For a general state in an hydrogenic atom Casimir obtains for the interaction energy

$$\Delta E = Rhc\alpha^2 Z^3/n^3(l + \tfrac{1}{2})j(j+1) \ g(i)/1840 \ ij \cos(i, j)$$

electrons have $n=2$ their interaction with the nucleus will be far smaller than that of the $1s$ electron, and will be neglected here

To obtain finally the hyperfine structure for the $1s\,2s\,{}^3S$ and $1s\,2p\,{}^3P$ states of Li^+, use is made of the expressions derived by Goudsmit and Bacher (*Phys Rev*, **34**, 12, 1929) Assuming for simplicity $i=1/2$, which does not affect the order of magnitude of our results, we expect to a first approximation

		Calc	Obs
${}^3S_1$	$\Delta\nu =$	$0\ 17\ g(i)$	$0\ 6\ cm^{-1}$
${}^3P_2$	$=$	$0\ 14\ g(i)$	$0\ 3$
${}^3P_1$	$=$	$0\ 085\ g(i)$	$0\ 3$

The result is that the expected separations are not of an order of magnitude 1840 times smaller than the multiplet separation of ${}^3P$, which is approximately $5\ cm^{-1}$

Recently Schuler and Brück (*Zeit f Phys*, **58**, 735, 1929) have given a tentative analysis of the Li^+ hyperfine structure leading to $i=1/2$, and giving the separations mentioned as observed in the above table With respect to the uncertainty in the screening effect and interpretation, their results indicate a $g(i)$-value of about 3 to 6 (It was hoped that this value would be approximately 2) The application of these formulæ to hyperfine structure in other atoms, which can be done to a first approximation by replacing $(Z/n)^3$ by Zz^2/n_0^3, also seems to lead to rather large values for $g(i)$

If the tentative interpretation of this hyperfine structure given by Schuler and Brück is correct, the hyperfine splitting is *inverted* Another example where this is the case is the cadmium isotope with $i=1/2$ (Schuler and Brück, *Zeit f Phys*, **58**, 737, 1929) This means that the magnetic moment of the nucleus is related to its mechanical moment as if it were due to *negatively* charged particles However, it is possible, though improbable, to have a complicated configuration of positive particles for which the resultant magnetic moment is oppositely directed to the mechanical moment Something similar occurs for the extra nuclear electrons in certain complicated configurations which show a negative Landé g value (for example, ${}^6F_{1/2}$, with $g=-2/3$)

Moment of Inertia of Hydrogen from Band Spectra

THE commonly accepted value of the moment of inertia of the hydrogen molecule, in the normal state, is due to Hori (*Zeit f Phys*, **44**, 834, 1927) In deriving this value, Hori expressed the rotational energy as $E_m = B_v m^2 + D_v m^4$, and calculated empirical values of D_v directly from the data The term $D_v m^4$ is due to the swelling of the molecule with rotation, and it is now well established that the theoretical values of D_v hold accurately in the case of electronic levels for which there is no resultant electron momentum to complicate matters This is the situation in the normal level of hydrogen (${}^1\Sigma$) Hori's values of D_v are several times as small as those given by theory and, what is more important, are positive, whereas a *swelling* of the molecule with rotation requires that they be negative Hori made note of this discrepancy in sign, but was unable to explain it We find, however, in agreement with Schaafsma and Dieke (*Zeit f Phys*, **55**, 164, 1929) that Hori's data, although relatively inaccurate and meagre, *do* indicate negative values of D_v, and we are unable to locate the origin of his published values It should be pointed out, in addition, that Hori's data give probable errors for B_v (his A_v) and D_v (his β) ten to one hundred times as large as his published errors for these quantities

There are now available much more extensive and accurate data for the normal state of hydrogen Schaafsma and Dieke (*loc cit*) have published rotational energy data, based on H_2 plates obtained by Dieke and Hopfield (*Phys Rev*, **30**, 400, 1927) on the 50 cm vacuum spectrograph at the University of California One of us (see H H Hyman and R T Birge, NATURE, **123**, 277, 1929) has recently obtained similar data from spectrograms taken with Prof Hopfield's new 10 ft vacuum spectrograph Using all available data from these sources, and employing the various known theoretical relations, we have calculated values of B as a function of v, and find

$$B_v = 60\ 587 - 2\ 7938(v+1/2) + 1\ 0500\times 10^{-2}(v+1/2)^2 - 24\ 058\times 10^{-4}(v+1/2)^3$$

In this equation, the actual vibrational energy levels are given by $v=0, 1, 2$, etc, and the available data run from $v=1$ to 12 inclusive The equation is entirely satisfactory from $v=1$ to 9 The higher values of v lie close to dissociation and the observed values of B_v are smaller than those given by the equation

The most important constant is of course B_0, corresponding to the lowest actual vibrational level ($v=0$) The absorption bands of the $B\ A$ system, observed and measured by Dieke and Hopfield (*loc cit*) lead directly to a value of B_0, but the probable error is quite large On the other hand, only one emission band (observed by Witmer, *Phys Rev*, **28**, 1223, 1926) is available for this purpose, and the data in this case are very fragmentary It is therefore necessary to evaluate B_0 by extrapolation, using the equation just given, with $v=0$ The extrapolation in this case is quite trustworthy *provided* the B_v curve is really smooth The result is $B_0 = 59\ 192\ cm^{-1}$ Using the new conversion factor $(27\ 66\pm 0\ 04)\times 10^{-40}$, given by Birge (*Phys Rev*, Supplement **1**, 1, 1929), one then obtains $I_0 = 0\ 4673\times 10^{-40}\ gm\ cm^2$, and $r_0 = 0\ 7500\times 10^{-8}\ cm$ Hori found $B_0 = 57\ 77$, giving $I_0 = 0\ 479\times 10^{-40}$ This differs from our value by 2 2 per cent

In this connexion we should like to emphasise that Hori's published $I = 0\ 467\times 10^{-40}$ refers to the true state of zero vibration ($v=-1/2$) and would now be denoted I_e Nearly everyone has quoted and used Hori's I_e value as though it were I_0 Our own value of B_e is given by the constant term in our equation (60 587), and this leads to $I_e = 0\ 4565\times 10^{-40}$, $r_e = 0\ 7412\times 10^{-8}$ It is interesting to note that Wang (*Phys Rev*, **31**, 579, 1928) obtained $I_e = 0\ 459\times 10^{-40}$, from a theoretical wave mechanics calculation We believe that the probable error in the values of B_1 to B_9, as given by the above equation, is 0 1 per cent, or less So far as the uncertainty of the extrapolation is concerned, the probable error in B_0 and B_e is not more than 0 2 per cent It is, however, shown in the following letter by Birge and Jeppensen that B_2 is definitely perturbed, so that our value is not correct Whether B_e is correct cannot be tested, since this constant refers to a molecular state which does not exist.

This work has been carried out with the advice and assistance of Prof R T Birge, to whom we wish to express our sincere thanks

Moment of Inertia of Hydrogen from Raman Effect

F Rasetti (*Phys Rev*, **34**, 367, 1929) has recently obtained accurate data on the Raman effect for gaseous hydrogen From his data it is possible to calculate extremely precise values of B_0 and B_1 This is very fortunate, for it is now possible, from band spectra, to obtain an accurate value of B_0 only by extrapolation, as has been shown in the preceding letter by Hyman and Jeppesen Because of the importance of this constant, it has seemed advisable to make a searching analysis of Rasetti's data, using all known theoretical relations

We have expressed the rotational energy as $E_m = B_v m^2 + D_v m^4 + F_v m^6$, where m is a half integer for the actual rotational levels We have calculated values of D_v from the theoretical relations derived by Kemble The only value of F which is known theoretically is F_e, but this can be used safely for F_v, when v is small We have also paid scrupulous regard to the difference between derivatives and finite central differences For most molecules the distinction can be ignored, but this is not at all the case for hydrogen Rasetti, in his calculations, omitted the $F_v m^6$ term, although his data clearly require it He also used D_v as constant, $= D_e$ Besides the rotational constants for $v = 0$ and 1, his data also evaluate $\omega_{1/2}$, the separation of these two vibrational levels, for zero rotation ($m = 0$) Using all of his data, we get $\omega_{1/2} = 4161\ 70$ cm $^{-1}$ Rasetti's value of 4161 8 is based on a single line

This value of $\omega_{1/2}$ is most interesting, for it lies definitely *off* the smooth ω_v v curve Hyman's new data have not yet been analysed for ω_v values, but the older data lead to $\omega_{1/2} = 4146$ cm $^{-1}$, with a probable error not greater than 2 cm $^{-1}$, so far as the extrapolation is concerned The discrepancy of 16 cm $^{-1}$, or 0 38 per cent, is therefore real Such a *vibrational* perturbation seems to be quite unprecedented, and obviously cannot be explained as due to the crossing of two sets of rotational levels Such a crossing, in any case, affects only certain *lines* of a band, and not the entire band Even the older data give 4159 cm $^{-1}$ for $\omega_{1/2}$, as one of us noticed several years ago, but Rasetti's work is the first to establish definitely the existence of this irregularity One disturbing consequence of the irregularity is that one cannot be certain of the value of ω_e, the frequency of vibration for infinitesimal amplitude In calculating D_v values, we have used $\omega_e = 4371$, as derived from a *smooth* ω_v curve, ignoring $\omega_{1/2}$ The resulting uncertainty in D_v is negligible, in any case

Our final calculated values of B_0 and B_1, from Rasetti's data, are 59 354 cm $^{-1}$ and 56 4035 cm $^{-1}$, respectively, as compared with Rasetti's published 59 40 ± 0 03, and 56 47 So far as the consistency of the data is concerned, our own calculated values have a probable error of less than 0 01 cm $^{-1}$, but the real probable error is doubtless several times as large Using all our derived constants, Rasetti's sixteen measured lines are represented with an average residual of 0 24 cm $^{-1}$ His own average residual is 0 36 cm $^{-1}$ The agreement with theory is remarkably close in every detail, and this is especially gratifying, since the hydrogen molecule provides the most severe test of any theory of band spectra

The equation for B_v, derived by Hyman and Jeppesen from band spectra data *only*, gives $B_1 = 56\ 4115$ cm $^{-1}$ This agrees with our value from Raman effect to *one part in seven thousand* It is the most accurate check between Raman effect and band spectra data that has yet been found, and is again a most satisfactory confirmation of theory On the other hand, the Raman effect value of B_0 is 0 27 per cent greater than the *extrapolated* band spectrum value The agreement of the B_1 values shows that the B_v equation given by Hyman and Jeppesen is entirely correct at $v = 1$, and hence its extrapolation to $v = 0$ is certainly correct to 0 1 per cent or less We therefore have a *perturbation* in the moment of inertia of the *lowest* vibrational state of hydrogen Since the separation of vibrational levels is assumed to measure an average value of the classical frequency of vibration in the two levels concerned, the conclusion seems almost inevitable that in the lowest vibrational level of hydrogen the frequency of vibration is *greater* and the moment of inertia *less* than the values to be expected from the constants for the other vibrational levels

The essential correctness of the value of B_0, as derived from Raman effect, cannot be questioned Hence the true I_0 for hydrogen is 0 46602 × 10^{-40} gm cm ^{2}, $r_0 = 0\ 74891 \times 10^{-8}$ cm These constants are given to five significant figures, like B_0, but it should be remembered that the conversion factor has itself a probable error of one part in seven hundred As noted by Hyman and Jeppesen, the value of B_e now becomes indefinite, due to the irregularity in B_0 but in the absence of contrary evidence, it seems best to use, for both B_e and ω_e, when calculating derived constants, the smooth extrapolated values already given

Raman Spectra of Crystalline Powders

In a recent communication (Nature, Nov 2, 1929) Prof R Bar of Zurich has shown that it is possible in many cases to photograph the Raman effect with solids in a state of powder The difficulty encountered by him, and also by Dr A C Menzies (see Nature, Oct 5, 1929), of the continuous background in the spectrum which overpowers all but the strongest Raman lines, is, however, serious, as it interferes with the general utility of the method During the past two months I have been engaged in an attempt to overcome this difficulty, and have found that it may practically be avoided by running the mercury arc at a lower temperature, and, where necessary, also by interposing a suitable light filter between the arc and the illuminated substance A concentrated solution of didymium chloride proved especially useful for this purpose Thus, for example, all the four lines obtained by Schaefer with a large single crystal of sodium nitrate may, with equal success, be photographed in about half an hour by using an irregular aggregate of small crystals placed within a small triangular shaped cell with mirrored walls

Prof Bär has found that in the case of naphthalene the Raman lines appear in the same position in the crystal powder as in the liquid My results with benzophenone crystals and liquid show that a marked change in the position of some of the Raman lines occurs on fusion of this substance, this is best seen with the line usually attributed to the ketonic group, which gives a shift of 1657 wave numbers in the liquid and 1650 in the solid, and is also noticeably sharper in the latter It is clear that a promising field of research offers itself in the comparative study of the Raman spectra in the liquid and solid states

About eighteen inorganic nitrates have also been examined by this method, some anhydrous and the others as hydrates It was noticed by Schaefer and by Bär that the inactive frequency of the NO_3 group in $NaNO_3$ crystals differed appreciably from the value in its aqueous solution In the present investigation, the largest shifts corresponding to the inactive frequency were given by lithium, sodium, and mag-

nesium nitrates (1071, 1070, and 1060 wave numbers respectively) The values obtained with calcium, barium, and lead nitrates were not much different from the value for nitric acid (1045), while mercuric and bismuth nitrates showed smaller frequency shifts (1037 and 1040 wave numbers respectively) In some cases, for example, lithium, aluminium, and mercuric nitrates, the line was accompanied by a fainter component

It is interesting to note that in nitrate crystals belonging to the cubic system the frequency shift is almost the same as for nitric acid in spite of the varying size of the metal atom (for example, calcium, barium, and lead nitrates) Of the other two frequencies, the 7 μ line appeared only in the case of lithium and sodium nitrates The 13 μ line, however, was more persistent and appeared in the case of lithium, sodium, ammonium, potassium, barium, and lead nitrates The Raman line corresponding to a remote infra red frequency appeared prominently in lithium and mercurous nitrates (42 9 μ and 57 2 μ respectively), and was also noticeable with sodium, calcium, barium, zinc, silver, and mercuric nitrates

P Krishnamurti

Raman Effect in Liquefied Gases

In a recent investigation by Daure (*Trans Faraday Soc*, **25**, 825, 1929) on the Raman effect in liquefied gases, it was found that the spectrum of liquid ammonia includes three strong lines the displacements of which are 321, 330, and 338 mm $^{-1}$ Two of these lines (321 and 330 mm $^{-1}$) have already been observed by Dickinson, Dillon, and Rasetti (*Phys Rev*, **34**, 582, 1929), who found the line 330 to be very strong and the other slightly weaker Now the Raman spectrum of ammonia vapour as reported by Wood (*Phil Mag*, **7**, 744, 1929) shows only the line 330 mm $^{-1}$, hence Daure ascribes the two new lines to some complex such as $H_3N = NH_3$ It seems to me that this observation is significant and worthy of more consideration

To begin with, it will be noted that the two new lines may be accounted for, within the limit of accuracy of Daure's measurements, by the expression 330 ± 8 mm $^{-1}$ This is precisely the sort of expression which gives the displacements of the Raman effect in general, and it suggests that the outer lines represent a scattering of the light which gives the central line by complex or associated molecules In other words, these lines may arise from a secondary Raman effect in the liquid Unfortunately, Daure reports only the 'negative' lines (displaced towards the red), so that no check can be made on the structure of these lines on the 'positive' side

The chance that this relation is mere coincidence is reduced by the data of Daure for liquid ethane, which exhibits in this region a similar triplet structure which may be represented by the expression 291 ± 4 mm So far as I am aware, the Raman effect in ethane vapour has not been reported, but if the viewpoint outlined above is correct, it should contain only the line displaced 291 mm $^{-1}$

One experiment which suggests itself as a confirmation of this interpretation is a determination of the polarisation of these lines If the two liquid lines have the same polarisation, it would be strong evidence that they are related in the manner suggested

If such an effect could be established, it would provide a valuable tool for investigating molecular complexes and associated liquids A few inferences on this basis will serve to indicate its power The frequency displacements of the liquid lines, ± 8 mm $^{-1}$ and ± 4 mm $^{-1}$ would indicate that the vibrations of the components of the complex are much smaller than those of the atoms in the molecules, which is to be expected Moreover, the fact that both positive and negative lines are quite intense would point to the existence of a considerable portion of the complexes in an excited state, probably closely akin to Henri's conception of 'predissociation' It is hoped that more data will shortly be available so that some of these questions may be settled

Raman Lines of Mercury in Arc improbable

A communication by Venkatesachar and Sibaiya appeared in Nature for Nov 30, 1929, in which the opinion was expressed that some of the faint nebulous lines of the mercury arc were in reality Raman lines of mercury excited by the more powerful radiations

This did not seem to me very probable, and I have investigated the matter with a new 220 volt quartz arc provided with a window of polished optical quartz which permits end on observation of the long narrow cylinder to which the discharge contracts when the arc operates on full load The region surrounding this highly luminous cylinder is comparatively dark, and would seem to be the most promising field in which to search for Raman lines

An end on image of the discharge was focused on the slit of a large quartz spectrograph by means of a quartz fluorite objective The image, a small circular disc of intense brilliancy, was blocked off with a strip of black paper, which was removed for half a second, at the end of the exposure The spectrum of the irradiated vapour above and below that of the disc was comparable in density with that of the discharge There was no relative enhancement of the lines indicated by Venkatesachar, if anything, they were a little stronger in the spectrum of the discharge than in the spectrum of the irradiated vapour

Raman Effect for Solutions of Sulphur Dioxide

Studies of the Raman effect for hydrogen chloride and for ammonia as gases, as liquids, and in aqueous solution have been made by various investigators With ammonia, the same modified line appears in all three cases Hydrogen chloride reveals the same scattered line in the liquid and gaseous states, but, as is to be expected, not in aqueous solution

We have investigated the scattering of sulphur dioxide in various solvents, such as water, benzene, and carbon tetrachloride, and intend to work with the pure liquid and the gas In addition to the modified lines arising from the solvent, there occur, in each instance, lines characteristic of the sulphur dioxide molecule The most prominent of these lines appear in all of the solvents at λ4588 and λ4238, excited, respectively, by λ4358 and λ4047 of the mercury arc The shift indicates an infra red wave length of 8 8 μ This is very close to the mean value of about 8 7 μ for the band from 8 4 μ to 9 0 μ, which is one of the most intense two of the six infra red absorption bands found by Coblentz for this gas

The replacement of the broad infra red band by a Raman line may be due to the faintness of the *P* and *R* branches in the spectrum adjacent to this line, and the appearance of a *Q* branch in the Raman spectrum, as was found by Wood for hydrogen chloride

Obituary

DR J G DE MAN

THE Dutch zoologist Dr Johannes Govertus de Man, who died at Middelburg on Jan 19 last in his eightieth year, was well known as an authority on two very diverse groups of animals, the free-living Nematode worms and the Decapod Crustacea

De Man was born in 1850 at Middelburg, where his father, Dr J C de Man, was a physician well known throughout the Netherlands He studied mathematics and natural science at the University of Leyden, where he received the degree of doctor in 1873 for a thesis, "Comparative Studies on the Myology and Neurology of Amphibia and Birds" He was appointed first assistant in the State museum of natural history in Leyden in 1872, and three years later was promoted to be conservator He had studied under Leuckart at Leipzig in 1872, and in 1876 he spent some months at the recently established zoological station at Naples, where, however, his stay was cut short by a severe attack of typhoid In 1881–82 he worked in Selenka's laboratory at Erlangen, studying the sipunculid worms collected by Semper on his expedition to the Philippine Islands

In 1883 de Man had to resign his post at the museum at Leyden owing to prolonged ill health and he retired to pursue his studies, first at his parents' home at Middelburg and later in a house which he built overlooking the Scheldt at Ierseke Here he lived the quiet life of the student, working out collections from museums and expeditions all over the world, appealed to by the neighbouring fishermen when anything out of the common came to their nets, and explaining to the children the nature of the treasures gathered on their seaside rambles Although he took no part in public life, his purse was ever open to appeals for charitable or useful purposes None could have been more courteous and helpful to those who sought information by correspondence, and none more careful to give acknowledgment for any assistance he received

The free living nematodes are a group little studied in comparison with those species that, by reason of their parasitic habits, come into more direct relation with human affairs, and few zoologists have any suspicion of their abundance or their variety In their study de Man was, after Bastian, one of the pioneers, and his work on them will not soon be surpassed for thoroughness and precision On the Decapod Crustacea, his numerous memoirs and papers, full of the most careful and detailed description and beautifully illustrated by his own pencil, remain as a mine of information for all students of the group An obituary notice in the *Nieuwe Rotterdamsche Courant* of Jan. 29 concludes with the words, "He leaves a blank, not only in the learned world, but also among the simple fisher-folk of Ierseke", a fitting epitaph for the kindly old scholar

W T C

LIEUT C B EIELSON

THE loss of Lieut Eielson removes one of the most experienced Arctic pilots and a pioneer in polar aviation On Nov 9 last year, he set out from Teller in Alaska on a second aeroplane journey to the ice-bound vessel *Nanuk*, off Cape North, Siberia On his failure to arrive, search parties were sent out, and during the month of February discovered the bodies of Lieut Eielson and his companion, Mr E Borland, near the wrecked machine about 90 miles south-east of Cape North

Carl Ben Eielson was an American of Norwegian descent In 1923 he was the first pilot to use an aeroplane in Alaska, and his success led to his being employed to carry mails during winter In 1926 he joined Mr (now Sir) Hubert Wilkins in his trial tests over the Arctic Ocean, which were continued in 1927 in preparation for a transpolar flight In that year they flew more than five hundred miles to the north west of Cape Barrow On the return, a forced descent on the pack ice was followed, after a second start, by another descent, which entailed leaving the machine and marching 75 miles over the ice to land This was done in two weeks, without any considerable difficulty

In 1928, Eielson piloted Wilkins's machine from Point Barrow via northern Greenland to Spitsbergen This was a flight of twenty hours and remarkable for its daring and skilful navigation In the same year Eielson went to the Antarctic with Wilkins and was his pilot in his 1200 mile flight in December, which resulted in the discovery that Graham Land is a series of islands

---

We regret to announce the following deaths

The Rt Hon The Earl of Balfour, F R S, Chancellor of the University of Cambridge and of Edinburgh, on Mar 19 aged eighty one years

Mr T A Barns, a well known Central African traveller and naturalist, on Mar 4, aged forty eight years

Mr R Moir Clark, until last year lecturer in agricultural botany at the University of Aberdeen and secretary for many years of the Aberdeen Natural History Society, aged sixty three years

Mr Edward Clodd, distinguished by his work and publications on folk lore and anthropology, on Mar 16, aged eighty nine years

Dr A T Hadley, emeritus president of Yale University and a distinguished economist, aged seventy-three years

Prof Maurice R J Hayes, professor of materia medica and therapeutics, University College, Dublin, and first Director General of the Irish Free State Army Medical Service, who was an authority on radiology, on Mar 2, aged fifty one years

Dr J B Hurry, formerly medical officer of Reading and author of a series of books on "Vicious Circles" which appeared in many languages, on Feb 15, aged seventy two years

Dr K J P Orton, F R S, professor of chemistry, University College of North Wales, on Mar 16, aged fifty-seven years

News and Views.

FOR the centenary meeting of the British Association for the Advancement of Science, which will be held in London next year on Sept 23–30, the Council has unanimously resolved to nominate Gen the Right Hon J C Smuts as president of the Association, and he has accepted the nomination It was felt that, for the London meeting, the president should be a leading statesman or other representative of the British Empire with scientific interests instead of being distinguished for work in a particular branch of science Usually, the presidents elected represent alternately the physical and the biological sciences, and little consideration is given to the appropriateness or otherwise of their special subjects to the place of meeting If the Prince of Wales had not been president of the Oxford meeting in 1926, he would obviously have been of unique significance as president of the centenary meeting in London His interests in South Africa suggest, however, that he would welcome the nomination of Gen Smuts, who is so very highly respected in that country

GEN SMUTS has wide interests in many fields of practical life and intellectual activity, and has won distinction in all of them He is a statesman with high principles and broad outlook, a naturalist who has done original field work in botany, and a philosopher who has correlated observations and conclusions into a coherent scheme His work on "Holism and Evolution", published in 1926, was a wide and original survey of evolutionary philosophy of a universe vitalised by a great driving force The great characteristic of the world of Nature is held to be the tendency to the development of 'wholes' The work revealed Gen Smuts as a scientific student and thinker of great knowledge and remarkable power of expression His presentation of Darwin's principles and discussion of the work and conclusions of Mendel and Weismann and their disciples showed both just appreciation and sound judgment, and his general thesis was a valuable contribution towards the merging together of science and philosophy Gen Smuts was president of the South African Association for the Advancement of Science in 1925, and in his presidential address on "Science in South Africa", the main part of which was published in NATURE of Aug 15, 1925, he presented a comprehensive survey of scientific problems of the southern hemisphere from the point of view of South Africa as the appropriate centre from which to correlate them Whatever may be the subject of his address at the London meeting next year, we are sure that it will be dealt with in a masterly way and will command the attention of all interested in progressive life and thought

PROF BOHUSLAV BRAUNER, the eminent Czechoslovak man of science, distinguished for his investigations in the chemistry of the rare earth elements, has just attained the jubilee of his 'promotion' as doctor of philosophy at the Charles University of Prague This event was celebrated according to the traditions of the University by a solemn renewal of his diploma on Feb 28 Prof Brauner has also recently been made an honorary member of the Polish Chemical Society, thus adding to the long list of foreign distinctions which have been conferred upon him in recognition of his researches in inorganic and analytical chemistry Among his more important discoveries mention may be made of his independent isolation of fluorine, carried out at Manchester in the early 'eighties, the recognition of the complexity of didymium and its fractionation into praseodymium, neodymium, and samarium He was among the first to realise the full significance of Mendeléeff's periodic classification of the elements and in support of it he undertook the redetermination of the atomic weights of many rare earth and other metals He had deduced, so early as 1877, that beryllium must be bivalent and therefore has the atomic weight 9, thus bringing it into line with Mendeléeff's scheme Prof Brauner's interest in the classification of the elements brought him into close contact with the Russian savant, and their intimate friendship only terminated on Mendeléeff's death Prof Brauner shares his countrymen's talent for languages, and writes with equal facility in six or seven European languages Many of his original researches have appeared in English journals, including NATURE Mention must also be made of his influence in Central Europe, for he has established, at the Chemical Institute of the Charles University of Prague, a school of research which maintains the high traditions associated with his work

IN the early part of the year 1830, Charles Lyell, F R S, foreign secretary of the Geological Society, published the first volume of the "Principles of Geology", and its centenary of issue and contemporaneous influence on scientific thought is worthy of recall Four years afterwards, the Royal Society awarded Lyell (he was not knighted until 1848) a Royal medal, with apt expression "For his work entitled 'Principles of Geology', in recognition of its comprehensive and philosophical spirit and dignity, and the important service rendered to science by specially directing the attention of geologists to effects produced by existing causes" As an exponent of the philosophy underlying geological study, and a historian of agencies in Nature he opened up new vistas for the men of his day During a period of forty years Lyell continued to enlarge and improve his work, bringing out no fewer than eleven editions "Which of us", asked Huxley, in his anniversary address to the Geological Society in 1869, "has not thumbed every page of the 'Principles of Geology'?" Lyell was born at Kinnordy, his father's seat near Kirriemuir, Forfarshire, on Nov 14, 1797 Educated at a private school at Midhurst, he graduated at Exeter College, Oxford, studying later for the Bar, though he never practised, his tastes leading him to geological pursuits Lyell was elected into the Royal Society in 1826, at the same time as Roderick Murchison He was created a baronet in 1864 He died at his home in Harley Street, London, on Feb 22, 1875, being then

in his seventy eighth year, and was buried in Westminster Abbey

ON Mar 29 occurs the centenary of the death of Major James Rennell, one of the most eminent of British geographers The son of an army officer, Rennell was born in 1742 at Chudleigh, Devonshire, and at the age of fourteen entered the Navy After some service in home waters, he was sent to the East Indian station, where he saw active service and gained considerable experience in the practice of marine surveying At the close of the Seven Years War he obtained his discharge from the Navy, entered the service of the East India Company, and in 1764 was appointed Surveyor General of Bengal and given a commission in the Bengal Engineers His labours were of great importance to Indian geography for, as the result of thirteen years' hard work, he was able to publish his Bengal Atlas, and in 1783 he published the first approximately correct map of India By that time, as a result of the climate and wounds, he had been retired on a pension of £600 a year, and for more than fifty years afterwards he lived in London, devoting his whole time to geography His house became the meeting ground of travellers and explorers, he was consulted by various bodies, and reports were sent to him from all over the world His writings on Herodotus, Troy, Asia, and Africa attracted much attention, and his work on currents and winds is recalled to every navigator by the Rennell Current which flows northward from the coast of France towards the Scilly Islands He was made a fellow of the Royal Society in 1781 and awarded the Copley Medal in 1791, he was also an associate of the Paris Academy of Sciences At his death he was buried in the nave of Westminster Abbey, where his bust and a memorial tablet are to be seen

AT the twenty second annual meeting of the Institute of Metals, held on Mar 12–13, Dr Richard Seligman was inducted as president for the current year Dr Seligman was born in London in 1878, and educated at Harrow and (1895) at the Central Technical College (City and Guilds Institute), under Prof H E Armstrong, he was awarded the College associateship in 1898 He then studied chemistry at the University of Heidelberg, and transferred to Zurich in 1900, being engaged in research work with Prof Eugen Bamberger Returning to Heidelberg he gained his doctorate in 1902 After a period in the Niagara Research Laboratories, N Y, he became chief chemist to the United States Zinc Company of Pueblo, Colorado In 1905 he commenced specialisation in his main work with his appointment as chief chemist to the British Aluminium Company, which appointment he relinquished in 1909 to form the Aluminium Plant and Vessel Co, Ltd, Wandsworth, London The activities of this concern have been devoted to the development of aluminium in the service of industry, originally in the welding processes which enabled large scale plant to be devised, and latterly in the associated technological work involved in its use in the foodstuffs, chemical, and other industries

HIS MAJESTY THE KING has approved the award of the Royal Medals for 1930 of the Royal Geographical Society as follows Founder's Medal to Mr F Kingdon Ward, for his geographical explorations and work on botanical distribution in south west China and south east Tibet, Patron's Medal to Mr C E Borchgrevink, for his pioneer Antarctic expedition of 1898–1900, which was the first to winter in the Antarctic, to travel on the Ross Barrier, and to obtain proof of its recession The Council of the Society has made the following awards Victoria Medal to M Emmanuel de Margerie, for his distinguished contributions to the science of land forms, Murchison Grant to Colonel H Wood, for his surveys with the Tibet Mission and the De Filippi Expedition to Central Asia, Back Grant to Mrs Gordon Gallien, for her expedition to the Kalambo Falls, Cuthbert Peek Grant to Mr Owen Lattimore for his travels in Mongolia and Chinese Turkistan, Gill Memorial to Lieut Col Reginald Schomberg, for his explorations in the Tarim basin and the Tien Shan

PROF R A SAMPSON, Astronomer Royal for Scotland, described the purpose and design of the new equipment at the Royal Observatory, Edinburgh, in a paper read before the Optical Society on Mar 13 The reasons which determined the form of the new telescope—a Cassegrain reflector of 36 inches aperture and 54 feet focal length, serving a spectrograph of one, two, or three prisms—were discussed, and the problems to which the instrument is to be applied were indicated Speaking generally, the main problem is the intensity of stellar light for different parts of the spectrum It was pointed out that even an empiric treatment of this question led Adams to a method that has doubled our knowledge of stellar distances A theoretical treatment, comprising a discussion of the behaviour of the photographic plate, led to fixing the temperature sequence A slit spectrograph is required in order to deal with the lines The state of the lines, combined with that of the continuous spectrum, conveys all the information that reaches us of the star's constitution and atmosphere Subsidiary but highly interesting questions are those of selective absorption of light by the atmosphere of the earth Behind these is the theoretical and laboratory investigation of the relation between intensity of light and the density of silver deposit on the photographic plate The whole presents an attractive field Mr C Young, of Messrs Sir Howard Grubb and Parsons, Ltd, described the reflector, and Mr J H Dowell, of Messrs Adam Hilger, Ltd, the spectrographic equipment

NEARLY a year ago a sub committee of the Committee of Civil Research was appointed, under the chairmanship of Mr E R Peacock, "to examine and report on the economic aspects of proposals for the construction of a Channel tunnel or other new form of cross Channel communication" A report has now been issued (Cmd 3513 London H M Stationery Office, 1930 3s net), signed by all the members of the committee, subject to a 'minute of dissent' by Lord Ebbisham It appears that only two schemes

were put before the committee, one of which is dismissed as impracticable and prohibitive in cost, while the other, due to the Channel Tunnel Co, is reviewed in detail The proposal is for two independent traffic tunnels each of 18 ft 6 in diameter and a pilot tunnel of 10 ft diameter for drainage and ventilation The tunnel approaches would be about 12 miles long and 24 miles would be under the Straits of Dover The cost of the pilot tunnel is estimated at £5,000,000 and the remainder of the workings at £25,000,000, the pilot tunnel would take about 2½ years to drive, and the whole scheme might be completed in 6½ years It will be remembered that the geological evidence on the possibility of constructing a Channel tunnel was discussed by Mr John Pringle in an article in Nature of April 20, 1929, p 608, wherein it was shown that, geologically, such a tunnel is practicable The committee of inquiry concurs with this view, but suggests that the final decision should await the completion of the pilot tunnel It is concluded that a Channel tunnel should be built and maintained by private enterprise and that it would be of economic advantage to Great Britain Lord Ebbisham, in his 'minute of dissent', opposes the scheme on economic grounds

In a lecture by Sir Harry Haward, the vice chairman of the Electricity Commission, to the Surveyors' Institution on Mar 10, a clear and interesting account was given of recent developments in the electricity supply of Great Britain Since 1920, the amount of plant installed in generating stations has been trebled and the cost of a unit to the consumer has been nearly halved To the non technical reader, the working of the scheme may be described as follows The merging of the general sources of a district provides a regional pool of electrical energy This pool is fed from selected stations operating under a definite control The more efficient stations work three shifts and take what is termed the constant load The less efficient stations work on a two or even a one shift basis Contributions to the pool are also derived from energy produced by waste heat from industrial works and other sources The central board purchases the whole of the output of selected stations and the owners buy back the amount required for their own use The rest of the energy is exported to those undertakers whose generating stations have been shut down For this purpose the grid, which is at 132,000 volts, is tapped at certain points where the voltage is reduced usually to 33,000 volts and from which lines radiate throughout the district The tapping of the grid is an expensive matter, costing at least £40,000, and cannot therefore be done merely to give supplies to individuals A breakdown at any station or an exceptional demand can at once be met by the resources of the pool The difficulties in the way of progress are connected with wayleaves, obtaining consents to the erection of overhead wires from local authorities and from the Council for the Preservation of Rural England Cases arise where the question of amenities has to be weighed against economic and utilitarian considerations The question is whether the boon of an electric supply will outweigh a limited interference with local amenities

Some interesting suggestions for the development of the resources of the British Empire have been put forward by Sir Robert A Hadfield in a pamphlet entitled, "Organised Empire Development", and in an article in *Canada* on "Making Empire Development a Business Proposition" As is well known, Sir Robert Hadfield advocates the formation of an Empire Development Board, non political and non-fiscal in character, which would investigate opportunities for trade and industrial development throughout the Empire This Board would be a permanent organisation, meeting more frequently than the Imperial Conference, and would consist of representatives from all parts of the Empire, devoting their whole time and energies to its work Meetings would be held in Great Britain and the various Dominions in rotation, and by this means the members would obtain first hand knowledge and experience of the conditions, requirements, and possibilities of the different parts of the Empire

In conjunction with the proposed Empire Development Board, Sir Robert Hadfield suggests that a large Imperial Development Fund should be raised which would be utilised by arrangement with the various governments to develop the productive capacities of the constituent parts of the Empire Among the first aims of the Board should be the promotion of the development of more efficient transport, the foundation of new industries, the initiation of hydro electric power schemes, the encouragement of agriculture and the control of forestry Attention should also be especially devoted to the economic development of the Crown Colonies, since in these areas raw materials in abundance can be obtained Another interesting suggestion put forward by Sir Robert Hadfield is that Empire settlers should be given opportunities to revisit the home country periodically This, he holds, would do a great deal to cement the ties of Empire

It is well to remind ourselves occasionally that there are technical colleges in Great Britain which are doing higher and more valuable work than teaching 'engineering arithmetic' or 'commercial English' to pupils who have left school without having acquired sufficient knowledge of arithmetic or English to do a simple calculation correctly or to write an intelligible letter, and who can only be tempted to further study by a title suggesting that a very little of an educational subject is sufficient for industrial or commercial life The January issue of the *Journal of the Royal Technical College*, Glasgow, gives ample evidence of the value for science and industry of the work which is being done at this institution It consists of more than 200 pages of research work carried out in the College by the staff and senior students and communicated to the *Journal* during the last six months of 1929 More than 80 pages emanate from the mechanical laboratory, 50 from the bacteriological, and the rest from the mathematical, chemical, physical, and pharmaceutical laboratories One cannot read these papers without realising the importance of the work which is being done in institutions of the type of the

Royal Technical College in the supervision and direction of present research and in training men for the research of the future

THE value of joint effort in scientific work is well illustrated by the success of the Southern Eastern Union of Scientific Societies The Union now consists of sixty-four societies interested in antiquities, architecture, botany, geology, natural science, photography, and the less circumscribed pursuits of field and rambling clubs, and in these it embraces more than sixteen thousand members It is probably not too much to say that few of these societies, standing by themselves, would accomplish much original work, but under the stimulus and organisation of union they have succeeded in doing well for the investigation of the south east of England The thirty third annual report, which appears for the first time with the title of the *South-Eastern Naturalist and Antiquary*, contains the papers read at the Brighton Congress of 1929—Sir Arthur Keith's presidential address on "The Pre Roman Inhabitants of Southern England", and the addresses of the presidents of sections But it also shows that the botanical section is compiling a complete flora of Sussex, and that the geological and archæological sections are alive to the need for collecting and recording local information and the discovery of objects of scientific interest This year's Congress is to be held at Portsmouth under the presidency of Mr O G S Crawford

AN interesting and important piece of evidence for the existence of the creature popularly called the 'sea serpent' has recently come to hand in the shape of a letter in which Capt F W Dean, R N (retired) describes a creature seen by himself and several of the officers and men of H M S *Hilary* in May 1917 He relates the incident as follows "About 9 A M on approx 22/5/17, H M S *Hilary* was some 70 miles S E of the S E part of Iceland, the day very fine and clear, the Iceland mountains in sight, flat, calm, and smooth sea An object was observed on starboard quarter The ship was turned round and steered straight for the object When we were about a cable (200 yards) from it the creature quietly moved out of our way and we passed it on our starboard side at a distance of about 30 yards, getting a very good view of it As we passed close to the creature it lifted its head once or twice as if looking at us The head was in appearance black and glossy, with no protrusions such as ears, etc, in shape about that of a cow the top edge of the neck was just awash, and it curved to almost a semicircle as the creature moved its head as if to follow us with its eyes The dorsal fin was a black equilateral triangle which rose at times till the peak was estimated to be four feet above the water"

THREE independent estimates made on board the *Hilary* gave the length of the neck of the 'sea serpent' (head to dorsal fin) as 15 feet or more, 20 feet, and 28 feet. The head appeared to have a patch of whitish flesh in front, "like that around a cow's nostrils" The dorsal fin was thin and flexible, occasionally curving over at the top The *Hilary* being on patrol at the time, the unfortunate creature was used as a target for anti submarine practice with the 6 pounders, at about 1200 yards range A direct hit having apparently been scored, it disappeared, no trace remaining A few days later (May 25, 1917), the ship was torpedoed and sunk, taking with her all logs, journals, etc, recording the 'sea serpent' incident As described, the creature seems to have borne a most striking resemblance to that seen off the Brazilian coast, in December 1905, from the Earl of Crawford's yacht *Valhalla* (see NATURE, June 28, 1906, p 202) This, also, exhibited a dorsal fin rising some four feet out of water, and a long, snake like neck, terminating in a head described as resembling that of a turtle In this case, the head and part of the neck were lifted well clear of the water, and not merely floating awash In both cases there seems no doubt that the observers saw a single living sea creature of unknown species

THE Journal of the American Museum of Natural History, New York, entitled *Natural History*, is the most successful popular museum magazine with which we are familiar, from the point of view alike of its matter and of its circulation The half dozen parts which form the volume for 1929 are remarkable for the variety of their interest, for the skill of the contributors in composing articles containing much now information expressed in easy language, and for the excellence and lavishness of the illustrations Where so much is excellent it is difficult to particularise, but one of the series most interesting to naturalists must be the descriptions and restorations of prehistoric animals recently discovered in America or in other parts of the world by the Museums' expeditions The final number for 1929, for example, contains an account, with photographs of the actual skeletons and of a restoration model, of a herd of Miocene camels (*Stenomylus hitchcocki*), discovered entombed near Agate Springs in Western Nebraska The cost of running so sumptuous a museum journal must be enormous, but the return, represented by interest taken in the Museum and its doings, must also be great, and much can be done with a membership numbering more than eleven thousand

SOME interesting data emerge in a study of the statistics of cancer in England and Wales, which have been published by M Pittard in the *Bull et Mém de la Société d'Anthropologie de Paris*, Ser 7, T 9, Fasc 4 5 6 This study is supplementary to an appendix in the Report of the Cancer Commission of the League of Nations and revises certain of the figures of distribution in that appendix Its chief interest, however, lies in the fact that M Pittard has here endeavoured to correlate the data of cancer and race He finds that the highest death rate from cancer for ages above forty five occurs in two groups of counties, (1) Montgomery and Merioneth in Wales, and (2) Rutland, Peterborough (Lincoln), Isle of Ely, Suffolk, Lincoln (parts of Holland), and Huntingdon On turning to the anthropological data, he finds that a high cancer rate is found with the higher figures for stature, and with the more pronounced dolichocephaly, but that in the case of pigmentation the figures are

contradictory, though certain of the data point to a coincidence of a high rate of cancer mortality and a high degree of nigrescence These conclusions are interesting for what they are worth M Pittard is well aware how far they fall short of a scientific standard The anthropological data upon which his conclusions are based are utterly inadequate In the case of pigmentation, there are whole areas for which he could obtain no data for his purpose, and he points out how completely Great Britain falls behind Germany, for example, in a knowledge of the physical type of its population Cancer, however, is but one of the more important of the numerous problems of which the scientific study is handicapped by the fact that no complete anthropometric survey of the British population has ever been made

At the annual general meeting of the Society of Public Analysts, held on Mar 5, the following officers were elected *President*, Dr J T Dunn, *Hon Treasurer*, Mr E B Hughes, *Hon Secretary*, Mr F W F Arnaud

The eleventh International Congress of Zoologists will be held at Padua on Sept 4–11 next, under the presidency of Prof Paolo Enriques It will be followed by two or three days' excursion to the valleys of Comacchio, Ferrara, Bologna, and Ravenna The office is at Padova, Via Loredan 6

Engineer Vice Admiral Sir Robert Dixon, president of the Institute of Marine Engineers, and Dr H J Weld, organiser of the Weld Ashmolean Expedition to Kish, have been elected members of the Athenæum Club under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

Dr Irving Langmuir, associate director of the General Electric Company's research laboratory at Schenectady, has been awarded the Willard Gibbs gold medal of the Chicago section of the American Chemical Society, " for fundamental work on atomic hydrogen and on surface relations and also on electrical discharge phenomena Also for his contributions of great importance to nearly all branches of physical chemistry, including high vacuum technique, electronics, thermochemistry, and catalysis And lastly, for his presentation of a theory of atomic structure "

In 1932 it will be a hundred years since the death of Goethe and fifty years since that of Darwin Goethe, it will be remembered, was a native of Frankfurt a/M, and Prof Fritz Drevermann proposes to arrange in the Senckenberg Museum there, of which he is director, an exhibition in commemoration of these two great men He would be glad to borrow for that purpose any objects personally connected with Charles Darwin, especially a page of his handwriting, and he urges that as a means of inducing friendship between the nations this last would have more value than " a scrap of paper "

Early this year it was announced in the daily Press that Prof A A Michelson, the distinguished physicist of the University of Chicago, had died, and we were glad to be able to contradict this report promptly and authoritatively Congratulations are now due to Prof Michelson on the recent award to him by the Council of the Physical Society of London of the Duddell Medal for 1930 This award, it will be remembered, is made annually to some one who has contributed to the advancement of knowledge by the invention or design of scientific instruments or by the discovery of material used in their construction Scientific workers generally will agree that this new tribute to Prof Michelson's genius has come at a particularly happy time

The Report of the Haffkine Institute, Bombay, for 1928 records that nearly two million doses of anti plague vaccine were issued, and 276,095 rats were examined for plague infection, of which 2222 were found to be infected At the anti rabic department, 718 persons were treated, of whom 6 died, a mortality of 0 83 per cent

By arrangement with the proprietors of *The Quarterly Journal of Mathematics* and *The Messenger of Mathematics*, the Oxford University Press will, after Mar 31, continue both journals by a single successor in new format, to be called *The Quarterly Journal of Mathematics (Oxford Series)*, and to appear quarterly, commencing in April next

Under the Local Government Act, 1929, the functions relating to public vaccination in England and Wales hitherto discharged by Boards of Guardians will, from the appointed day (April 1, 1930), be transferred to other bodies The Ministry of Health has, therefore, issued an explanatory leaflet (*Circular* 1067) to guardians of unions extending into more than one area, and to the county and other councils who will assume the functions of the guardians, a statement of the main statutory provisions governing the vaccination service (*Memorandum*, L G A 33, 2d) The Minister of Health has also issued an Order (Order No 73,990 Statutory Rules and Orders, 1930, No 2 9d net) consolidating and amending the orders made from time to time under the Vaccination Acts, 1867 to 1907 with a covering circular (*Circular* 1068) All these publications are issued by H M Stationery Office

The latest catalogue (No 341) of Messrs W Heffer and Sons, Ltd, Cambridge, to reach us contains particulars of some 2500 second hand works, mainly relating to the classics and classical archæology, from the libraries of the late H V Macnaghten and R D Hicks

Applications are invited for the following appointments, on or before the dates mentioned —An assistant master, graduate in engineering, at the Ashton under Lyne Junior Technical School—G W Handforth, Education Offices, 8 Warrington Street, Ashton under Lyne (Mar 29) A sanitation officer for Barbados—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 An assistant radiologist at London Hospital —The House Governor, London Hospital, E 1 (Mar 29) An organic chemist as research assistant

at the East London College—Dr A Robertson, East London College, E 1 (Mar 30) Scientific officers and junior scientific officers under the Directorate of Scientific Research of the Air Ministry—The Chief Superintendent, R A E, South Farnborough, Hants (April 5) An assistant in the Jodrell Laboratory at the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (April 7) An assistant lecturer in mathematics at the University College of Hull—The Secretary, University College, Hull (April 14) Professors of botany, and geography and anthropology, at the University College of Wales, Aberystwyth—The Secretary, University College of Wales, Aberystwyth (April 23) A lecturer in palæontology and stratigraphy, two lecturers in geography, and a demonstrator in inorganic and physical chemistry, at Bedford College for Women—The Secretary Bedford College for Women, Regent's Park, N W 1 (April 24) Three assistant inspectors of ancient monuments under the Commissioners of His Majesty's Works and Public Buildings—The Establishment Officer, H M Office of Works, Westminster, S W 1 (May 16) A radiologist at the Wellington General Hospital, New Zealand—The Secretary, Wellington General Hospital, Wellington, New Zealand (May 20) Two assistant physicists, one a woman, under the Research Association of British Paint, Colour, and Varnish Manufacturers—The Director, Paint Research Association, Waldegrave Road, Teddington A sanitary inspector under the Sudan Medical Service—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W 1 A radiologist at the Mount Vernon Hospital—The Secretary, Mount Vernon Hospital, 7 Fitzroy Square, W 1 A woman assistant under the Air Ministry, Kidbrooke, for Aeronautical Inspection Directorate Test House—Secretary, I E 2, Air Ministry, W C 2

Our Astronomical Column

New Comet, 1930 *b*.—The second cometary discovery of the year was made at Hamburg on Mar 11 by Mr Beyer, the magnitude was given as 10½, but as the object was seen in bright moonlight it may have been brighter than this Subsequent search of plates exposed by Dr Prager at Neubabelsberg, Berlin, revealed images The following positions are from telegrams from the I A U Bureau, Copenhagen

	U T		R A	N Decl	Observer	Place
Mar	2^d	21^h $59{\cdot}0^m$	6^h 8^m $12{\cdot}86^s$	28° 3′ 5″	Prager	Berlin
	8	21 11·0	6 7 40·53	28 32 2		
	11	20 30·5	6 5 20	32 22	Beyer	Hamburg
	13	18 49·9	6 5 11·33	33 14 2	Bianchi	Milan

The comet is well placed in the evening sky, and should be within reach of moderate instruments

M Ebell has computed the following orbit and ephemeris of Beyer's comet, they have been telegraphed from the I A U Bureau

$$\begin{array}{ll} T & 1930 \text{ April } 22{\cdot}212 \text{ U T} \\ \omega & 26° \quad 41' \\ \Omega & 116 \quad 26 \\ i & 71 \quad 28 \\ \log q & 0{\cdot}31385 \end{array}$$

EPHEMERIS FOR 0^h

	R A	N Decl
Mar 21	6^h 5^m 56^s	36° 13′
25	6 7 12	37 45
29	6 9 8	39 11

There does not appear to be any sensible deviation from a parabola in the orbit of comet 1929 *d* (Wilk) Mr F E Seagrave deduced an orbit from observations extending over five weeks, which indicated a period of 20,000 years

Mars in 1926.—Prof W H Pickering has for many years published in *Popular Astronomy* reports on the successive apparitions of Mars His report on the 1926 apparition appeared in December last Thirty six drawings by eight different observers are reproduced These are arranged in groups some 60° apart in longitude, so that drawings of the same region are grouped together While there are large differences in style, the drawings of the separate observers to a large extent corroborate each other, some differences are due to real changes on the planet, produced by clouds, or precipitation from them The great majority of the canals on the drawings are confirmed by different observers, though some draw them much narrower than others The total number of canals drawn was 189, of which 139 were confirmed by other observers The lakes seem less certain, 110 were drawn, but only 69 confirmed Prof Pickering notes that the apparition of 1928 was probably the worst observed one in modern times, still he exhorts observers to send him such drawings as they were able to make, as it is undesirable in the interests of continuity that it should pass unrecorded

The Zodiacal Light.—Two interesting notes about the appearance of this phenomenon have come to hand In *Astr Nach*, 5684, Mr I Yamamoto reports the observations of two Japanese astronomers, K Araki and T Kamei, on the morning of Nov 3, 1929, the former noted that at 76° from the sun its width exceeded 40° and its brightness was twice that of the galaxy in Auriga The latter noted that at 80° from the sun the width was 23°, and the brightness five times that of the galaxy in Monoceros Nearer the sun it appeared to be narrower and fainter, that may be due to lower altitude Twilight had not begun at either station The axis of the light lay very near the ecliptic according to Mr Araki, Mr Kamei noted that the base was on the ecliptic, but the apex some 6° to the south of it

In a letter to the Editor, Mr C T Jacob, stationed at Tuticorin, South India, states that about local midnight on the night of Jan 30–31, 1930, the zodiacal light was visible simultaneously in the east and in the west, the appearance was that of two nebulous triangles, the apices of which pointed to the zenith, the western triangle was brighter and better defined than the other The sky was so clear that the Milky Way could be traced right down to the horizon in the south Mr Jacob notes that there are no powerful artificial lights in his neighbourhood that could have given rise to the glows that he describes

The late Mr E W Maunder, in his account of the eclipse expedition of January 1898, noted that the zodiacal light was frequently very conspicuous in India

Research Items.

The Earliest Bantu.—The problems of the Bantu languages and the light they throw upon the earliest culture of the Bantu speaking peoples are discussed by Dr N J v Warmele in *Africa*, vol 3, No 1 The Bantu languages constitute a group of exceptional uniformity both in grammar and vocabulary, which indicates that they are derived from one clearly distinct form of speech From the comparative study of living Bantu dialects, philologists have reconstructed archaic or Ur Bantu From this may be deduced a knowledge of the ideas and the culture, and perhaps the place of origin of the ancient Bantu The roots now accepted as belonging to the Ur-Bantu tongue number nearly a thousand These indicate that the original home of the early Bantu was by a lake (root *yangja*, for example, Nyassa, Nyanza) Neither the names of animals nor plants are helpful, as they are too widely distributed throughout the whole continent, but the roots for the names of animals exclusively African are widely spread, so that the Ur-Bantu were familiar with them from an early date If, therefore, they came from Asia, it must have been before their language began to split up, and the infancy of Ur Bantu may safely be laid in Africa As regards the nature of their culture, the root *Yombe*, meaning cattle, is of wide distribution, and cattle must therefore have been known long ago But in South Africa the root for cattle, *Komo*, is related to the Hottentot *goma b*, *kumamb* Further, it is only in the South African languages that the root for sheep occurs to any extent, suggesting that the Bantu obtained their sheep from the Hottentot The widely distributed terms for breeding or rearing apply only to cattle On the other hand, the Bantu were not cattle breeders simply, and a similar examination of the roots indicates that agriculture also played a part in the economic life of the people The grain with which they have been longest acquainted is millet, and their agricultural implement the hoe The evidence would also point to the fundamental religious conception as being taboo Although *túla*, 'to forge iron', is common, there is no term for iron, and the word *túmbi* in use in South Africa also means cowrie, so that apparently iron was not known to the early Bantu, and when introduced was used through barter, and primarily served the purpose of currency and ornament only

Vocational Guidance in Schools.—In the *Journal of the National Institute of Industrial Psychology*, vol 5, No 1, there is a suggested scheme for the organisation of vocational guidance in schools It is no longer necessary to defend vocational guidance as such, its value in numbers of cases has been well established There is, however, the very practical problem of providing assistance in the selection of a career for large numbers The article suggests that in every school there should be one person whose recognised duties should include the vocational guidance of the children He should work in consultation with his colleagues, the parents, and the school medical officers As, however, no one person could obtain all the necessary information about all possible careers and industrial facilities, his work should be supplemented by that of a visiting vocational adviser, who should be responsible for the vocational guidance work in all the schools in his district He should be the originator of new lines of inquiry, of experimentation with new tests The suggestions put forward in the article are worthy of serious consideration

Inheritance of Natural Immunity.—The literature on natural immunity in animals and its inheritance has been summarised by Mr A W Kozelka (*Jour of Heredity*, vol 20, No 11), who points out that immunity to a particular disease may be characteristic of a species, a race, or an individual Many curious cases of specific and racial immunity are cited The immunity of the frog to anthrax is at least partly due to the phagocytic activity of its leucocytes, while the blood serum of animals often has a bactericidal effect The alligator is immune to tetanus because of a natural antitoxin in its blood Such human diseases as diphtheria, typhoid, scarlet fever, measles, and yellow fever are not found in animals Larvæ of the rhinoceros beetle were found by Metchnikoff to be susceptible to cholera but immune to anthrax and diphtheria, while crickets are readily susceptible to anthrax Among related species, *Anopheles maculipennis* carries malaria, while *A punctipennis* is immune Negroes are relatively immune to yellow fever, and Japanese to scarlet fever Negroes are very susceptible, and urban Russians, Poles, and Jews much more resistant to tuberculosis Measles is a fatal disease among various native races Such racial differences have probably resulted from natural selection through long exposure to the disease Among domestic animals, the Algerian sheep is the only breed not susceptible to anthrax Zebu cattle are apparently unaffected by foot-and mouth disease, anthrax, and Texas fever, and the immunity is transmitted in some degree in hybrids with ordinary cattle The Japanese waltzing mice are susceptible to implanted tumours, while the degree of resistance in house mice varies greatly in different localities Many rats are immune to plague Some 50 per cent of human beings and 30 per cent of horses are naturally immune to diphtheria By selection, strains of mice resistant to mouse typhoid can be produced, or of guinea pigs resistant to tuberculosis In many of these cases several Mendelian inheritance factors appear to be involved

Fishes of the North Atlantic.—The International Council for the Exploration of the Sea, at the Copenhagen meeting in June 1928, decided to undertake the publication of an illustrated ichthyological fauna of the North Atlantic Parts 1 and 2 of this work have now appeared ("Faune ichthyologique de l'Atlantique Nord" Conseil Permanent International pour l'Exploration de la Mer (Publiée sous la direction de M le Professeur Joubin) N p n d) It is published in the form of loose cards made up in sets of 24 Each set or part is enclosed in a folder, and the entire work is expected to run to about 15 parts One card is devoted to each species and contains, in addition to one or more illustrations, a clear and precise description of the fish, its geographical distribution, synonymy, and a short bibliography The legend is written—in English, German, or French—by specialists on the group or family concerned, and each card is signed by the author Some of the illustrations are original, others are reproduced from standard works It seems unfortunate, however, that more original illustrations are not being produced, especially when some of those copied from elsewhere could be replaced by better illustrations

Mammals of Buru, Moluccas.—For the first time a list of the mammals of Buru has been published, and it reveals a fauna of unusual interest (Dr K. W

Dammerman in *Treubia*, Buitenzorg, vol 7, Suppl, December 1929) Of the 27 species recorded, 16 are bats, and of the four rats and mice, three are recorded for the first time from the island The most interesting species are undoubtedly the Moluccan deer (*Cervus hippelaphus moluccensis*) and the Babirussa Buru is the type locality of the former, although the race seems now to be very rare there, and may have been imported in former days Dr Dammerman regards Buru as the type locality also of the Babirussa, for although Linnaeus described the species as from Borneo, the older Dutch authors do not mention its presence there, and the Dutch name Boeroe for Buru may have led to confusion It is curious that, in spite of the frequency with which skulls of this species may be found in museums, the skin of the beast itself is so rare Even the museum at Buitenzorg has only an old and badly stuffed specimen from Celebes and a recent damaged skin from Buru The unexpected and localised distribution of the species on the island and the fact that it has no native name suggests that at one time it may have been introduced from Celebes, for Quoy and Gaimard stated that in former times the rajahs there kept and bred the babirussa in order to make presents of it The shortness of the skull and less straight profile of the Buru race may be, as in domestic pigs, indications of domestication

A New Japanese Oyster —Dr Haruo Seki has discovered a new species of *Ostrea* from Japan which he has named *Ostrea futamiensis* ("Description of a New Species of Oyster from Japan", *Proc Imp Acad Sci*, Tokyo, vol 5, No 10, 1929) This oyster is to be found with *Ostrea denselamellosa*, and has hitherto been regarded as a dwarf form of that species The new oyster, bearing the Japanese name of *Kuro himegaki*, has a much larger egg than *O denselamellosa*, although the shell in the adult is much smaller The spat is either uniformly black or striped with yellow The developmental stages take place within the mantle cavity until the free swimming straight hinge larval stage is reached, the larvæ when freed being found near the shore in the deeper water layers So far as has been observed, each individual spawns twice or thrice at intervals of from ten to twenty days during the spawning season, which lasts from the middle of June to the end of September

Taxonomy of Bryophyta —In "Honduran Mosses collected by Paul C Standley" (Field Museum of Natural History, Chicago, Pub 267 Bot Series, vol 4, No 9, 1929), Edwin B Bartram describes 178 mosses, representing 79 species and including four new to science, *Campylopus hondurensis*, *Bryum Standleyi*, *Bryum bursiforme*, and *Rhynchostegium patulum*, which are figured and described The data are too meagre for a discussion of geographic distribution, but Mr Bartram considers the evidence points to affinity with Mexico and the Antilles rather than with the types of Costa Rica and Panama It is suggested that *Isopterygium scalpellifolium* (C M) Broth should be restored to *Microthamnium*

Hybridism in the Forests of New Zealand —In no country is the knowledge of hybridism in the native flora so advanced or the recognition of its all-important bearing upon floristic and ecological botany so fully appreciated as in New Zealand, where Dr Cockayne's researches have done so much towards a proper understanding of its taxonomic significance In a recent paper (*Acta Forestalia Fennica*, 34, 1929), he gives details concerning the forest and semi forest hybrids, more than a hundred groups of which have been recognised. Cogent reasons are advanced for accepting the hybrids as valid, and in several cases hybrids have been synthesised which match those occurring in the field With one exception, so far as is known, all the hybrids are fertile, and the constant crossing and segregation which takes place results in the hybrid groups all occurring as big polymorphic swarms of individuals which have previously been either aggregated into so called 'variable' species, or segregated into inconstant varieties The rôle of the hybrids in the forest is discussed with reference to the number and relative abundance in the community of the hybrid groups and the life forms of the hybrid individuals which are present

Development of the Inflorescence in Cereals — Very valuable data on this subject are provided by Yakichi Noguchi for Japanese cereals in a paper in the *Journal of the College of Agriculture*, University of Tokyo, 10, 247 303, 1929 Detailed measurements of the inflorescences at various stages are supplied, together with details of morphological development for six spring sown and four winter sown cereal types under Japanese conditions A study of the rice plant's development under various conditions of cultivation shows that the developmental characteristics vary very little, which adds force to the general conclusion that spring and winter sown types show very different types of development In all the cereals the initials of the reproductive organs are already to be detected in the embryo in the mature grain In the spring sown types, a very slow growth of the panicle initial occurs for the first 40 50 days, and during this time the morphological changes in the growing point are negligible Growth and differentiation then start suddenly and proceed very rapidly until the panicle emerges from the bud In the winter sown types, on the contrary, shortly after sowing, floral parts begin to differentiate in the panicle initial, although growth is slow for the first 120 150 days Then rapid growth begins and proceeds for some 65 days longer, when the panicle emerges from the bud No correlation was found between the vigour and period of vegetative development, and the processes of floral differentiation and development, on the other hand, a large grain showed correlation with a large embryo and a large embryo with the degree of differentiation of the floral rudiments within it On the basis of a comparison of the growth and development of their floral organs, Noguchi would put rice, sorghum, panicum, and setaria into one group wheat, rye, barley, and oats in another, with maize yet another distinct type The data supplied in this paper are very full and valuable, and will well repay close study

Salinity Investigations in the South African Seas — Mr Marchand has shown (*Fisheries and Marine Biological Survey* Report No 6 For the Year 1927–28 Special Report No 4 Pp 1-21) that water samples can be analysed within three months without any appreciable inaccuracy in the results, and confirms Dr Gilchrist's statement that "the Mozambique Current, which has been subjected to the evaporation of the equatorial regions, contains a greater percentage of salt than the Antarctic waters" which is known as the Benguela Current on the west coast This difference in salinity has not been observed to have a direct effect on life in South African seas, but the existence of waters of different temperature and salinity side by side forms an effective barrier to some animals

Echo Sounding and Depths —In an article on echo sounding in the *Hydrographic Review*, vol. 6, No. 2, Dr H Maurer raises a practical issue of much import

ance In order to calculate the true echo distance, obtained by a sonic sounder, the mean velocity of sound between the ship and the bottom must be known The velocity varies with temperature, salinity, and pressure Tables for conversion of echo distances to depths are issued by the Admiralty (H D 282), and comparisons made by the German vessel *Meteor* in recent work in the South Atlantic showed that the use of these tables gives fairly accurate results in cases where the depths was ascertained by both echo and wire Yet out of 245 comparisons of depths of more than 2000 metres, 36 gave a difference exceeding 100 metres and the maximum difference was 650 metres The echo gives, of course, the distance to the nearest point on the bottom, and not necessarily the vertical depth Since depths are frequently important in finding position, Dr Maurer suggests that the echo distances should be entered on the chart The crude echo distances, converted on a single constant velocity, are the most useful to the seaman and also for scientific purposes since it is then possible to convert them by the latest data available Results of echo sounding given in depths without any indication of the velocity on which the depths are based or of attempts to rectify oblique distances are practically useless and may be misleading

A New Lamp —The February issue of the *General Electric Review* contains a description of a new form of electric lamp, in which an arc and filament are operated together The arc passes between terminals of tungsten in an atmosphere of mercury vapour and pure argon, and the filament, a V shaped spiral of tungsten, is connected internally in the same bulb between the electrodes of the arc In the lamp for which details are given, about two thirds of the light emitted comes from the tungsten electrodes, and one quarter from the arc, the remainder being presumably from the filament The colour temperature of the light is greater than 3500° absolute The tube passes a current of about 30 amperes at 11 volts, and is self starting Ultra violet light of physiological value has been conserved by making the bulb of a special iron free glass, which is partially transparent down to a wave length of 2800 A

The Charge of an Electron —Prof A S Eddington's derivation of the amended number 137 for the atomic constant $hc/2\pi e^2$ is given in a paper entitled "The Interaction of Electric Charges" in the March number of the *Proceedings of the Royal Society* As he indicated in his letter to NATURE on this problem (Nov 30, 1929, p 840), the mistake in his earlier theory (see NATURE, Jan 26, p 138, and Feb 2, p 174, 1929) consisted not so much in overlooking that degree of freedom of a pair of electrons which has no counterpart in the theory of a single electron—alteration of the proper distance between the two—as in not recognising its distinctness from the others Whether or not the best *experimental* value of the constant is 137 is still perhaps an open question In addition, by making definite assumptions as to the physical significance of certain transformations and results of quantum theory, Prof Eddington has traced down the distinction between space and time to properties of matrices, the matrix theory predicts that one dimension of the world will be related to the other three by Lorentz transformations instead of by rotations Still another tentative line of argument points to an origin of the loss of mass which occurs in such cases as the formation of the nuclei of atoms, in the loss of a degree of freedom when charges link up to form a *perfectly rigid* system Prof Eddington's aim in this paper has been to substitute a more satisfactory geometrical basis for the appeals to the analogies of classical dynamics which occurred in his earlier theory, but he expresses the opinion that finality has yet to be attained

Iridescent Colours in Nature —The discourse on iridescent colours given by Lord Rayleigh at the recent exhibition of the Physical and Optical Societies at the Imperial College of Science has been published in full —apart from the illustrations—in the February number of the *Journal of Scientific Instruments* The objects dealt with were chiefly butterfly wings, beetles, and the eye of a peacock feather That the colours of butterflies are partly due to absorption and partly due to interference is well established, but the origin of the colours of an iridescent beetle has been a matter of controversy The facts presented by Lord Rayleigh seem to establish that they are due to interference in a laminated structure, and not to surface reflection, for quite apart from the variation of the colour with the angle at which the beetle is viewed, the characteristics of the banded spectrum of light transmitted by a specimen are those of an interference spectrum All the observations mentioned by Lord Rayleigh are not yet completely explained, however, in particular, the bleaching of what are apparently interference colours by exposure to ultra violet light, or even to sunlight, calls for further investigation, and especially the complicated behaviour of the peacock's feather, in which, under such treatment, certain zones have their reflecting power for red light *increased*

Origin of Protoactinium —The January number of the *Journal of the American Chemical Society* contains an important paper by J E Wildish on the separation of tantalum from different uranium ores, this element being the nearest homologue of protoactinium The uranium and protoactinium contents of five uranium ores from widely separated localities were determined and the atom for atom relation between uranium and protoactinium computed in each case The results show that the ratio in different ores is very different, and consequently lend support to the hypothesis that the actinium series originates from some other source than uranium II

Ignition of Hydrocarbons in Oxygen —It is now generally recognised that paraffin hydrocarbons react readily with oxygen at comparatively low temperatures In the January number of the *Journal of the Chemical Society*, J S. Lewis describes some experiments in which mixtures of hydrocarbon vapour and oxygen were heated in glass bulbs until explosion occurred It was found that in dilute mixtures explosion could not be produced, but extensive oxidation had occurred at about 235°, and the rate of heating was also important The minimum percentage for ignition increased with the instability of the hydrocarbon towards oxygen With rich mixtures the explosion was not so violent the violence increased with reduction in hydrocarbon content until a maximum was reached when the ratio approaches that for complete combustion A more rapid rate of heating tends to raise the ignition temperature, a result not found with olefines In presence of powdered charcoal the ignition temperature of paraffin is raised, that of amylene considerably lowered In presence of lead tetraethyl the ignition temperature was raised, some times as much as 40° It is concluded that the explosion of hydrocarbons takes place in two stages, the explosion of the products of autoxidation (peroxides or chain reactions) followed by the combustion of the products in the excess of oxygen to oxides of carbon and water

The Articulation of a Telephone Circuit.

THE best method of testing telephone circuits and apparatus is a problem to which a great deal of attention has been devoted of recent years. Speech is carried over a telephone circuit by means of certain frequency components produced by the voice of the speaker at the sending end and received by the listener at the receiving end. If the components arriving at the listener's ear are exactly the same as when they left the speaker's mouth, the circuit would have a hundred per cent efficiency. There are two principal reasons, however, why the components arriving at the listener's ear are not the same as those leaving the speaker's mouth. In passing along the circuit the amplitude of the waves is attenuated, they thus become weaker. The amount of the attenuation also varies with the frequency, and hence the waves become distorted. Again, components which were not originally present are produced in the circuit. These are due either to noise or to the overloading of some part of the circuit. Their effect is to raise the threshold values at which the ear can hear different notes. In *Electrical Communication* for January, J. Collard gives a method by means of which the effect of given noises on the 'articulation' of a telephone circuit can be computed much more quickly than by the ordinary methods.

In the usual method of testing, a series of syllables chosen at random are spoken into the telephone, the listener writing down what he imagines he hears. The ratio of the number of syllables correctly received to the total number of syllables sent gives an indication of the quality of the circuit. Unfortunately, the value thus obtained depends not only on attenuation and distortion, which are produced by the circuit, but also on faulty pronunciation by the speaker and faulty hearing by the listener. The value, therefore, varies with the speakers and the listeners, a great number of tests have to be taken before we can tell what is the approximate mean value.

The author gives empirical formulæ by means of which the ideal sound articulation can be approximately computed. It is not affected by careless pronunciation by the speaker or inattentive hearing by the listener. Once a circuit has been set up, articulation tests can be made on it and the value of the articulation obtained, but there are many cases in which it is desired to know before installing a given circuit or before inserting a given piece of apparatus in the circuit what the articulation will be, and this can be found in a few minutes by the author's method.

It has been calculated that to obtain a value of the articulation with a probable error of one per cent, it is necessary to speak 5000 syllables into the circuit. If there are ten pieces of apparatus to be tested, this would mean that 50,000 syllables would have to be called. The usual rate of calling is 20 per minute. Taking into account also the time required for calibrating the experimenters the total time will be about 50 hours. The saving effected, therefore, by using the new empirical formulæ is a substantial one. In a previous paper published in *Electrical Communication* for January of last year, the author showed that articulation has much the same value whether English, French, German, or Italian be used. It appears, therefore, that his method is applicable to other languages with little, if any, modification.

Whaling and Fishing in the North Atlantic[1]

IN the autumn of 1923 the Norwegian Government appointed a whaling committee, under the chairmanship of Dr Johan Hjort, to carry out a scientific study of whaling and of the various factors in the sea which govern the life and migrations of whales. This committee at once approached the British Discovery Committee with a proposal that the two bodies should co-operate in this work. As a result of the negotiations which followed, it was agreed that, at any rate to begin with, the best arrangement would be for the *Discovery* to operate on the Antarctic whaling grounds, especially those worked from the Falkland Islands Dependencies, while the Norwegian investigators concentrated upon work in the North Atlantic.

In accordance with this agreement, a number of investigations have been carried out in northern seas during the years 1924–1928 under the administrative direction of the Norwegian whaling committee, the results of which have now been published in a very full report of some 550 pages. This report, although entitled "Whales and Plankton in the North Atlantic", deals not only with the occurrence and distribution of whales and their food but also with the occurrence and habits of the various species of fish of economic importance.

The two great sea areas lying west of Greenland (Davis Strait) and to the eastward of it (Norwegian Sea) have been studied in detail. Reference is made at the outset to two cruises made by Jensen during the summers of 1908 and 1909 in the brig *Tjalfe*, when that indefatigable investigator prospected for fish along the entire western seaboard of Greenland, including fjords, inshore waters, banks, and deep sea—a vast tract extending from 60° N. to 71° N. Along this enormous distance the distribution and biology of all the more important edible fishes were investigated, and the fact established that the very limited fishery of this region is due not to the absence of marketable fish but to the primitive equipment of its fishermen and their difficulty in disposing of their catch. There is an abundance of good fish, including common cod, fjord cod, halibut, Greenland or black halibut, the long rough dab, and two species of catfish.

During the years 1924–28 fishing expeditions to Davis Strait, financed by Messrs. I. O. and O. S. Hellyer of Hull and led by Mr. Engvald Baldersheim of Bergen, have proved extraordinarily successful, and form striking examples of what can be done to solve the difficult problems of organisation involved in fishing in very distant seas. To this region Hjort proceeded in the research vessel *Michael Sars* in 1924 and there carried out exhaustive fishing and hydrographical investigations.

The course of modern whaling is traced from the time of its initiation by Svend Foyn in Finland about the year 1870 until the present day, when its operations extend to almost all the waters of the globe. In a section written by Andr. Ingebrigtsen, himself a practical whaler of more than thirty years' experience, it is shown that with few exceptions the commercial pursuit of the whale sooner or later reduced the stock so greatly that whaling had to be abandoned either temporarily or permanently as unremunerative. Convincing details of the growth and decline of many whale fisheries are given. From about the year 1880 onwards, a number of whaling stations were established along the coast of Finmark and the number of boats rapidly increased from four in 1880

[1] Whales and Plankton in the North Atlantic (a contribution to the work of the Whaling Committee and of the North Eastern Area Committee). Conseil Permanent International pour l'Exploration de la Mer. *Rapports et Procès-Verbaux des Réunions*, Volume 56. Pp. 551. (Copenhague: Andr. Fred. Høst et Fils, 1929.) 21.50 Kr.

to thirty-four in 1885 The fatal result of this increase in the intensity of the fishery was soon apparent, for after about the year 1900 whaling at most of the Finmark stations ceased to pay and steadily declined In 1905 most of the companies transferred their headquarters to Bear Island and Spitsbergen, but there too the industry was not of long duration Too many boats destroyed the fishery, and by 1910 fishing in these waters was entirely abandoned Subsequent attempts to revive the industry at Spitsbergen in 1920 and 1925-26 proved ruinous to the companies concerned

Whale fishing off Iceland commenced about the year 1890 with eight whaling vessels The catch at first was good and the number of boats increased to thirty in 1902 Thereafter there followed a steady decline in the catches One station after another had to close, and Iceland whaling ceased altogether in 1915 The history of the whale fishing at the Faroes is in many ways similar to that of Finmark and Iceland As the number of boats increased the catch per boat greatly decreased, and many stations ceased to operate But during the War whaling stopped to a large extent This proved good for the stock, and post War catches off the Faroes, with fewer boats as compared with the number employed before the War, have yielded reasonable profits

The same tale of rapid initial growth and subsequent decline is told of whaling in the Straits of Gibraltar, off South Africa, and on the west coast of America, and in a final sentence Ingebrigtsen states his firm conviction that the great modern extension of whaling in the Antarctic will undoubtedly, in spite of its vast tracts of ocean and apparently enormous numbers of whales, produce in the course of some years the same results as in all other waters—namely, a decreasing stock of whales from year to year G A S

University and Educational Intelligence

CAMBRIDGE —At King's College the following have been elected to Fellowships Mr A E Ingham, reader in mathematics at the University of Leeds, and Mr R F Kahn, Wrenbury Scholar (1928) and Adam Smith prizeman (1929)

CARDIFF —H R H the Prince of Wales will visit Cardiff on May 21 to open the new chemistry and physics wing of the University College, and the Department of Public Health of the Welsh National School of Medicine

Mr H J Phelps has been appointed as assistant lecturer and demonstrator in physiology

EDINBURGH —On the recommendation of the Faculty of Medicine, the Cameron Prize for 1930 has been awarded to Dr George R Minot, physician in chief, Collis P Huntingdon Memorial Hospital of Harvard, Boston, Mass , and Dr William P Murphy, assistant physician, Peter Bent Brigham Hospital, Boston, Mass , conjointly, for their work on the liver treatment of pernicious anæmia

The Senatus has resolved to offer the honorary degree of doctor of laws to the following, among others Sir Thomas Barlow, Physician Extraordinary to H M the King , Sir Otto Beit, trustee of the Rhodes Trust and founder of the Beit Memorial Fellowships for Medical Research , Sir William Hardy, director of food investigation, Department of Scientific and Industrial Research , Sir David Wallace, consulting surgeon to the Royal Infirmary, Edinburgh , Prof. W W Watts, professor of geology, Imperial College of Science, South Kensington , Prof K F Wenckebach, emeritus professor of medicine, University of Vienna

Historic Natural Events.

Mar 23, 1233 Thunderstorm and Floods —There was a great and terrible tempest of thunder, and after followed a marvellous wet summer with many floods

Mar 23, 1913 Electrical Storm —An usually severe electrical storm occurred in the western part of Kansas, U S A High winds were blowing from south west or west, and the air was warm, very dry, and filled with dust , there was no rain Windmills, especially steel mills mounted on wooden supports, became so highly charged with static electricity that anyone touching them received a distinct, sometimes a severe shock At Tribune, sparks two or three inches long were drawn from a wire running to a windmill Telephone and telegraph wires and wire fences also became charged, and in Scott County, where the disturbance was most severe, a prairie fire is thought to have been started by sparks at a break in a wire fence, as in several places distinct sparks were noted on holding the broken ends of wire fences together In Thomas County all green vegetation was killed, and in Sheridan County the wheat turned brown The sky was obscured by a leaden or copper coloured haze, and most people experienced nervous depression

Mar 24, 1878 *Eurydice* Squall —A V shaped trough of low pressure crossed England from north west to south east, and with its passage the wind changed from a moderate westerly breeze to a north westerly gale The wind velocity was not especially great, but there were some violent north-westerly squalls with sleet or snow, during one of which the training ship H M S *Eurydice* foundered with all hands off Dunnose Head, near Ventnor The loss of life was about 300

Mar 24, 1895 Gale —This was described as the worst gale of the nineteenth century in the English Midlands At 8 A M , a well marked depression was centred over the Shetland Isles, and during the afternoon a small but intense secondary depression traversed England and Wales with a velocity of 58 miles per hour The greatest destruction was caused by a south westerly gale along a narrow belt (only 30 50 miles in width) to the right or south east of the track followed by the centre of the secondary Very great damage was done to property, many churches were injured and thousands of trees uprooted, and several lives were lost In the observatory at Birmingham the oscillation of the building stopped the clock

Mar 25, 1241 Drought —It is recorded in Matthew Paris's Chronicle that "From the Annuciation to SS Simon and Jude (Mar 25-Oct 28), continued drought and intolerable heat dried up deep lakes and extensive marshes, drained many rivers, parched up the warrens, and suspended the working of mills, hence the pastures withered away, herbage died, and consequently the flocks and herds pined away with hunger and died"

Mar 26, 1812 Earthquake in Venezuela —The town of Caracas was utterly ruined by an earthquake felt throughout Venezuela and as far as Carthagena (600 miles) The shock occurred shortly after 4 P.M As it was Ascension Day, large crowds had collected in the churches before the processions through the streets began, and three or four thousand persons were killed by the fall of the roofs Throughout Venezuela, more than 20,000 persons perished On April 24, the first eruption of the Soufrière of St Vincent since 1718 began The noise from it was heard at Caracas (nearly 400 miles)

Mar 27, 1606 Great Storm in Belgium.—At 8 A.M. began a great tempest of wind which continued

until 2 or 3 P M, and especially from 9 A M to 1 P M, during which time the great force of the storm threw down chimneys and very great trees, and unroofed almost all the churches and a great part of the houses It blew with such fury that one expected every minute to perish, and it surpassed the storm of Mar 27, 1524

Mar 28, 1916 Gale and Snowstorm in England – Great numbers of elm trees in the southern and midland counties were uprooted, railway traffic was dislocated in the midlands on the Midland, L N W R, and G W R lines in consequence of snowdrifts and wrecked telegraph wires The snowfall was general throughout England and Wales, and greatest in the hill districts, where many villages were isolated, and farms and sheep buried beneath gigantic drifts, in some cases 40 feet deep In the Black Mountains the snow was 10 feet deep

Societies and Academies

LONDON

Royal Society, Mar 13 — **V B Wigglesworth** A theory of tracheal respiration in insects The theory provides for the increased demands for oxygen which arise locally in active tissues If it be assumed that the terminal portions of the tracheal tubes are bounded by a semi permeable membrane then liquid will be drawn up the tubes by capillarity until further progress is checked by osmotic pressure of the tissue fluids During activity lactic acid will be produced, osmotic pressure will rise, liquid will be absorbed and air will extend down the tubes towards the active tissues The theory is supported by experiments on mosquito larvæ (see NATURE, Dec 28, 1929, p 986) Some observations are recorded on the effects of certain poisonous gases and of oil on the tracheal system — **H Raistrick** and others Studies in the biochemistry of the lower fungi A résumé of the main results of investigations presented in eighteen papers communicated to the Society

Geological Society, Feb 5 — **E J Garwood** The Tuedian Beds of northern Cumberland and Roxburghshire east of the Liddelwater The series consists of sandstones, mudstones, shales, and impure limestones laid down mainly under lagoon conditions An interesting feature is the important algal development in the middle of the series The beds are intermediate in character between the freshwater facies of the Tweed district and the more marine facies of Westmorland The succession is described under three districts Northern Cumberland (Bewcastle district), Roxburghshire (Newcastleton district), Western Northumberland (Rothbury) In northern Cumberland the structure is that of a denuded anticline having a general north north easterly trend This area may be divided into two districts separated by the 'central' fault The Bewcastle district in the east is taken as the type, and the succession has been determined there The algal episode enters first in the Bewcastle Beds, but the conditions were unfavourable, and it is not until the Main Algal Series is reached that algal growths become important as rockbuilders In Roxburghshire east of the Liddelwater, the algal series is again well developed In Northumberland, the chief feature of interest is the rich development of *Mitcheldeania* and *Ortonella* near the summit of the Cementstone Group, the latter genus being especially characteristic of the highest two limestones in the neighbourhood of Rothbury — **Sir Douglas Mawson** and **C T Madigan** Pre Ordovician Rocks of the McDonnell Ranges (Central Australia) This paper concerns the age and stratigraphical relations of a great series of quartzites, slates, and limestones forming the southern front of the McDonnell Ranges These beds, dipping at a steep angle off the older Pre Cambrian basement (Arunta Complex) of the Ranges, extend in an east and west direction with wonderful regularity for a length of at least 150 miles This great series of rocks lies stratigraphically between the undoubted Ordovician rocks (Larapintine formation) and the Arunta Pre Cambrian Complex They form a Pre Ordovician series, upon which rests unconformably the Larapintine Formation with its basal members formed of conglomerates and breccias Horizons rich in Cryptozoa and *Girvanella* like algal growths characterise the series

Institute of Metals, Mar 12 (Annual Meeting) — **T A Rickard** The early use of the metals The industrial history of mankind is divisible into two major epochs— a stone age and a metal age The melting of copper probably preceded its extraction from minerals by some centuries and the production of bronze or hardened copper was a later stage in metal culture The critical event in the industrial history of man was the first melting of metal out of stone, and this appears to have occurred about 3500 B C Metal articles fashioned at earlier periods were made from native gold, silver, or copper, or from meteoric iron — **D Stockdale** The composition of eutectics A very sensitive apparatus for the taking of cooling curves is described, and a new method for the determination of the liquids from such curves is given The eutectic systems examined were as follows aluminium copper, antimony silver, cadmium tin cadmium zinc, copper silver, and lead tin — **N P Allen** Experiments on the influence of gases on the soundness of copper ingots The unsoundness in commercial ingots is not due to hydrogen alone but to hydrogen and cuprous oxide together which react in the solidifying metal to evolve steam Those elements which, when added to copper, endow it with the ability to cast soundly, do so by reducing the cuprous oxide present Carbon monoxide, carbon dioxide, and nitrogen are inert, so far as the formation of blowholes is concerned — **W E Prytherch** Gases in copper and their removal Experiments on the effect of oxygen, hydrogen, and sulphur dioxide on the soundness of copper Dissolved gases may be partially removed by (1) Slow solidification followed by remelting of the copper, (2) passing an inert gas, such as nitrogen, into the molten metal, (3) melting *in vacuo* Experiments to determine whether oxygen would remove hydrogen showed that the rate of oxidation was so slow as to make the method unpractical — **E J Daniels** Unsoundness in bronze castings The effects of some pure gases on the soundness of bronze, and of casting in sand moulds of metal subjected to various melting treatments, are described Nitrogen, carbon dioxide, and carbon monoxide are neutral towards bronze Hydrogen is capable, at certain rates of solidification, of causing unsoundness which can be suppressed by treatment with neutral gases Improvement in density of sand castings can be obtained by melting in a pot furnace with a thin fuel bed and good draught Degasification with nitrogen deoxidisers, and pre solidification gave negative results so far as improvement in density is concerned, but pre solidification appears to increase the strength — **R Genders** Macrostructure of cast alloys Effect of turbulence due to gases When an alloy is cast in a mould prepared by a coating of volatile material, the macrostructure of the resulting ingot may be considerably modified by the turbulence resulting from the evolution of gases by the mould coating

DUBLIN

Royal Irish Academy, Feb 24—**Joseph Algar and Mary Boylan** Azo dyes derived from diaceto resorcinol The preparation of some azo derivatives of diacetoresorcinol and of dichalkones is described Diazonium salts couple readily with diacetoresorcinol in alkaline solution forming compounds with tinctorial properties The latter condense with aromatic aldehydes under the influence of alcoholic hydrochloric acid or piperidine with the production of dichalkones containing an azo group, for example, phenyl azo dianisylidene diacetoresorcinol All the compounds described function as dyestuffs and give yellow to brown shades on mordanted wool—**Joseph Algar and A V Flaegel** The action of Grignard reagents on phthalide By the carefully regulated addition of o methoxyphenyl magnesium bromide to phthalide and decomposition of the resulting addition compound, the substance produced is α hydroxy α (2-methoxyphenyl) β, β′ benzo α, α′-dihydrofurane (I), a compound which very readily loses water with the production of complex dehydration products Reduction of I with sodium amalgam gives 2 methylol 2′-methoxy diphenyl carbinol (II) The addition of phthalide to an excess of the above Grignard reagent gives 2 methylol 2′, 2″ dimethoxy triphenyl carbinol (III) Dehydration of III with hydrochloric acid gas gives α-di (o methoxyphenyl) β, β′ benzo α, α′ dihydrofurane (IV) The latter, in benzene solution, exhibits a beautiful blue fluorescence

PARIS

Academy of Sciences, Feb 10—**Serge Bernstein** The limitation of derivatives of polynomials—**Louis Roy** The propagation of waves on elastic surfaces with six parameters—**Bertrand Gambier** Configurations—**Paul Delens** The representations of circles—**N Lusin** The problem of J Hadamard on the uniformisation of ensembles—**L Kantorovitch and E Livenson** The δs functions of Hausdorff—**Henri Cartan** Functions of two complex variables and the encircled domains of Carathéodory—**Miloch Radoitchitch** The fundamental domains of meromorph functions—**Lucien Féraud** The extension to the case of any number of degrees of freedom of a property relative to Pfaffian systems—**N Cetajev** The reciprocal of Lagrange's theorem—**Jean Courrègelongue** The formation of eddying movements behind immersed solids—**G Mouret** The conditions of passage through a section of a permanent current (of fluid), open, uniform, or gradually varied—**Henri Mineur** The movement of the double stars under the action of the field of gravitation of the galaxy—**G Ribaud** The calculation of the temperature of flames and their proportion of atomic hydrogen A calculation of the influence of the dissociation of hydrogen into atomic hydrogen on the temperature of flame The cases of hydrogen and oxygen and acetylene and oxygen are considered—**E Darmois** The action of boric acid and borates on the rotatory power of tartaric acid Boric acid has no action on ethyl tartrate, but borax at 40° C has a clear action The author agrees with the views of Lowry as to the constitution of these complex compounds—**Mlle Stéphanie Maracineanu** Remarks on a note by MM Fabry and Dureuil entitled "On a supposed transformation of lead" Reply to criticism, maintaining the accuracy of the original results—**G Reboul** A method of activation of matter The activation of metals described in an earlier note by treatment with high voltages has been proved by further experiments to be independent of the nature of the metal and of the conditions of working, and the origin of the activity appears to be in the air—**A Astruc, M Mousseron, and Mlle N. Bouissou** A new method for the micro estimation of the calcium ion The method, which is applicable for the determination of quantities of calcium between 0 1 mgm and 1 5 mgm, is based on the precipitation of the metal as the tungstate, reduction of the latter by titanous chloride, followed by comparison of the colour produced with a known standard—**Lespieau and Bourguel** A new ethylenic erythrite The new erythrite is

$$CH_2(OH)\ CH(OH)\ CH=CH\ CH(OH)\ CH_2(OH)$$

and is obtained by the reduction of the corresponding acetylene compound with hydrogen in the presence of colloidal palladium—**Louis Glangeaud** The age of the strata containing Orbitolines at the north of the province of Algiers—**Henri Termier** The vertical extension of the genus *Spiriferina* in Morocco From the evidence adduced it is concluded that this genus persisted in Morocco for a much longer period than in the north east of Europe—**Raymond Furon** The presence of copper in the French western Sudan—**Guilliermond** The formation of zoosporangia and the germination of the spores in *Saprolegnia*, in cultures on nutritive media containing neutral red Neutral red is a colouring matter which is almost non-toxic and is of great value for the study of vacuoles—**M Bridel and C Charaux** Oroboside, a new glucoside hydrolysed by emulsin, extracted from *Orobus tuberosus*, and its products of hydrolysis, glucose and orobol The products of the hydrolysis of oroboside by emulsin are glucose and a substance, orobol, described in detail It appears to be a tetra hydroxyflavone further work is in progress with the view of determining its exact constitution—**H Lagatu and L Maume** Observation, by leaf diagnosis, of the phenomenon of mutual physiological replacement of two bases, lime and potash—**Lenglen and Durier** Appreciation of the value of powdered limestones used in agriculture The solubility of a limestone in a solution of carbon dioxide in water under fixed conditions depends largely on its physical structure as well as on its state of division The correlation between carbonic acid solubility and neutralising action on the soil has been proved—**Charles Pérez** Visceral asymmetry and dimorphism of the spermatophores in some pagurians—**Mlle Simone Mouchet** The comparative morphology of the excretory canals of some pagurians—**P Portier and Mlle de Rorthays** The mode of flight of insects and the wing load per unit of surface There is a striking concordance between the modes of flight of various insects and their anatomo physiological characteristics—**H Simonnet and G Tanret** The toxicity for laboratory animals of large doses of irradiated ergosterol The toxic action of irradiated ergosterol on rabbits was found to be associated with a calcification of the arterial system, but the venous system and the pulmonary artery remained free from calcification Owing to the varying toxic action on different animals, no conclusion can be drawn as to the action on human beings—**F Labrousse and Mlle S Philippon** Phenomena of oxido reduction observed in the course of the development of some fungi—**H Bierry** Proteid sugar and mannose in mammals

CRACOW

Polish Academy of Science and Letters, Dec 2—**K Kordylewski** The variable stars Orionis 47 1929 and 49 1929—**Mlle H Grünbaum** New resonance of selenium.—**P. Swings** The structure of the groups of resonance lines of sulphur vapour.—**L Marchlewski and A Boryniec** The absorption of ultra-violet radiations by the methoxybenzoic acids The absorption in the ultra violet by *p* methoxybenzoic acid

is much more intense (about six times) than that given by the meta isomer —K Dziewonski, J Auerbach, and J Moszew 1, 8-Benzyl benzoyl-naphthalene and some of its derivatives —M Thomaschewski The pollen analysis of the peat bogs of Sztengwald and of Zaskoczyn (Free Town of Dantzig) The results obtained are analogous with those found for southern Sweden —S Skowron Researches on spermatogenesis *in vitro* —A Wierzejski The fresh water sponges —T Marchlewski Genetic researches on the domestic dog

Diary of Societies

FRIDAY, MARCH 21

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Lecture Room, Imperial College of Science and Technology), at 2 30 —The Nutrition of Fruit Trees —T Wallace Some Effects of Deficiencies of Essential Elements on Fruit Trees —R G Hatton Response of Apple Trees on known Rootstocks to Applications of a Complete Fertiliser —N H Grubb The Reaction to Potash Fertilisers of Apple Trees in the Field —Dr T Swarbrick Some Observations upon the Growth and Seasonal Cycle of Food Reserves in Apple Trees

DIESEL ENGINE USERS ASSOCIATION (at Caxton Hall), at 3 30 —H R. Ricardo The High Speed Diesel Engine

IMPERIAL COLLEGE CHEMICAL SOCIETY (at Royal College of Science), at 5 —Prof I M Heilbron The Fat Soluble Vitamins A and D (Lecture).

LONDON SOCIETY (at Royal Society of Arts), at 5.—Dr R. Unwin The Decentralisation of Industry

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section) at 5 —Dr C W Buckley and others Discussion on The Influence of Sunlight and other Climatic Factors in Health and Rheumatic Diseases

BRITISH INSTITUTE OF RADIOLOGY (Medical Section), at 5 —Discussion on Radiology in Chest Diseases

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir Frank Colyer Demonstration of Specimens Illustrating Dento alveolar Abscess and Dental Cyst

INSTITUTION OF MECHANICAL ENGINEERS, at 6 —W Nithsdale The Design and Results of a 660 lb per sq in Boiler Installation

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne), at 6 —Sir Westcott Abell Direct Flooding Calculations

INSTITUTE OF MARINE ENGINEERS, at 6 30.—Annual General Meeting

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at St. Thomas Café, Swansea), at 7 —Annual General Meeting

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at 36 George Street, Manchester), at 7 —A. J Hall The Effect of Swelling Agents on the Creasing of Artificial Silks —J R. Hannay The Preparation of Artificial Silk and Cotton Unions for Printing.—Eva Hibbert On the Action of Certain Acids on Cellulose —J H Preston The Mounting of Textile Fibre Sections.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) (Informal Meeting), at 7.—A. J. Gibbons and others: To Meter or not to Meter.—W. Lawson and others: Whether or not Meters should be Stamped and Sealed.—E. Fawssett and others: The Use of 1 amp. Secondaries in Current Transformers as against 5 amp. Secondaries.—C. H. Green and others: Whether or not Prepayment Meters should be Earthed.—G. F. Shotter and others: Formula for the Merit factor of a Meter.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group—Informal Meeting), at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Students' Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.15.—J. Bennett and O. A. Chrisp: A Survey of Switch and Control Arrangements with Examples of Modern Practice.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7.30.—M. V. Hurst: Surface Combustion.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8.—Dr. J. E. Hughes: A Case of Hydatidiform Mole with Multiple Synoytial Infarction of the Lungs.—Dr. A. F. Gyles: The Influence of Hysteropexy on Subsequent Pregnancy, and of Pregnancy on a Previous Hysteropexy.—Prof. W. F. Shaw: The Treatment of Prolapsus Uteri.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Dr. J. M. W. Morison: Diaphragmatic Hernia.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Seton Gordon: Sea Birds and Seals.

PAPER MAKERS' ASSOCIATION (Technical Section, Northern Division) (at Engineers' Club, Manchester).—N. L. Matthews: The Application of Dyestuffs to Paper.

SATURDAY, MARCH 22.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire District) (jointly with North Western District) (at Town Hall, Halifax), at 2.15.—F. Marsden: Borough and County Borough Extensions in the Light of the Local Government Act, 1929.

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College), at 3.—C. L. Beaven and others: Discussion: Are we satisfied with the Present Syllabus in Mathematics for the General School Certificate?

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Nuclei and their Structure.

MONDAY, MARCH 24.

KING'S COLLEGE ENGINEERING SOCIETY (Anniversary Meeting), at 5.30.—Brig.-Gen. M. Mowat: A Brief Review of Mechanical Engineering Progress in the Past Thirty-four Years.

BRITISH PSYCHOLOGICAL SOCIETY (Joint Meeting of Industrial and Education Sections) (at National Institute of Industrial Psychology), at 6.—The Relation of Raising the School Leaving Age to Problems of Vocational Guidance and Selection.—Miss Sheila Bevington (from point of view of Vocational Guidance), F. Tibbey (from point of view of Education).

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (Annual General Meeting) (at Great Northern Station Hotel, Leeds), at 7.—Dr. N. K. Adam and others: Discussion on The Fundamentals of Lubrication.

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7.

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—H. A. Humphrey, D. M. Buist, and J. W. Bansall: The Imperial Chemical Industries Limited's Steam and Electric Power Plant at Billingham.

ROYAL SOCIETY OF ARTS, at 8.—Comdr. F. G. Cooper: Aids to Navigation (Cantor Lecture) (1).

MEDICAL SOCIETY OF LONDON, at 8.—Sir Thomas Horder, K. Walker, and others: Discussion on Coliform Infections of the Genito-urinary Tract.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Sir William Willcox: Dental Sepsis—a Retrospect.—F. Coleman: Buried Mandibular Teeth with Crowns in Occlusion.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Dr. E. Trinkler: Exploration in the Karakoram and Kun Lun.

TUESDAY, MARCH 25.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Meeting), at 4.30.—O. J. R. Howarth: The Work of the British Association in Relation to the Empire.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. C. F. Coombs: Syphilis of the Heart and Great Vessels (Lumleian Lectures) (2).

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5.—Prof. E. Leschke, Dr. J. Parkinson, Dr. J. Cowan, Dr. T. F. Cotton, and others: Discussion on Syphilitic Aortitis.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. C. Singer: The Passage from Mediæval to Modern Science (3): On the Inductive Philosophy and some of its Instruments.

INSTITUTION OF CIVIL ENGINEERS, at 6.—D. Anderson: Tyne Bridge, Newcastle.—G. I. Groves: The New Wearmouth Bridge, Sunderland.

BRITISH PSYCHOLOGICAL SOCIETY (Industrial Section) (jointly with Education Section), at 6.—Discussion on Vocational Guidance and Selection in Relation to the Raising of the School-leaving Age, with papers dealing with the question from the point of view of (*a*) Education, (*b*) Vocational Guidance and Selection, (*c*) Industry.

ROYAL AERONAUTICAL SOCIETY (at 7 Albemarle Street), at 6.30.—Annual General Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre) (at Loughborough College), at 6.45.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—H. A. Humphrey, D. M. Buist, and J. W. Bansall: The Imperial Chemical Industries Limited's Steam and Electric Power Plant at Billingham.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—W. Clark: The Characteristics of Sound Recording Emulsions.—W. Clough: The Pantone Process of Reproduction.

ILLUMINATING ENGINEERING SOCIETY (at Home Office Industrial Museum, Horseferry Road, S.W.1), at 7.—S. Anderson: Textile Lighting.

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7.30.—F. W. Rowe: Common Defects in Steel for Gear Manufacture.

WEDNESDAY, MARCH 26.

CHEMICAL SOCIETY (at Salters' Hall, E.C.), at 5.30.—Prof. G. von Hevesy: The Chemistry and Geochemistry of the Titanium Group (Hugo Muller Lecture).

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—W. Campbell Smith: A Classification of some Rhyolites, Trachytes, and Phonolites from Part of Kenya Colony, with a Note on some Associated Basaltic Rocks.—Dr. T. N. George: *Ambocœlia* Hall and certain similar British Spiriferidæ.

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at 17 Fleet Street), at 5.30.—A. Titley: Winding Engines of Richard Trevithick.

INSTITUTION OF CIVIL ENGINEERS (Students' Meeting), at 6.30.—P. J. Pollock: Nomography as Applied to Engineering.

INSTITUTION OF AUTOMOBILE ENGINEERS (Manchester Centre) (at Engineers' Club, Manchester), at 7.—Capt. J. S. Irving: Problems Encountered in the Design of the *Golden Arrow*.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—E. G. Lowes: The Development of Auxiliary Machinery as applied to Ships.

HALIFAX TEXTILE SOCIETY (at Halifax), at 7.30.—Discussion on Education.

ROYAL SOCIETY OF ARTS, at 8.—H. Robertson: Architecture of To-day and To-morrow.

EUGENICS SOCIETY (at Royal Society), at 8.30.—Dr. J. A. Ryle: Constitution as a Factor in Morbidity.

THURSDAY, MARCH 27.

CHEMICAL SOCIETY (Annual General Meeting), at 4.—Prof. J. F. Thorpe: Presidential Address.

ROYAL SOCIETY, at 4.30.—Discussion on Geological Climates opened by Dr. G. C. Simpson, followed by Prof. A. C. Seward, Prof. J. W. Gregory, Sir Peter Mitchell, C. E. P. Brooks, and Dr. C. Tate Regan.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. C. F. Coombs: Syphilis of the Heart and Great Vessels (Lumleian Lectures) (3).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—J. B. S. Haldane: Some Problems of Genetics.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—H. H. Harrison: Developments in Machine Telegraph Systems and Methods of Operation.

BATLEY AND DISTRICT TEXTILE SOCIETY (Annual General Meeting) (at Batley Technical College), at 7.30.—H. R. Hirst: Faults in Yarns and Cloths, their Detection and Prevention.

MEDICO-LEGAL SOCIETY (at 11 Chandos Street, W.1), at 8.30.—Prof. J. S. Haldane: Carbon Monoxide Poisoning and its Medico-Legal Aspects.

ROYAL AERONAUTICAL SOCIETY (Yeovil Branch).—Aircraft Accessories.

INSTITUTE OF RUBBER TECHNOLOGISTS (at Manchester Café, Ltd., Manchester).—H. Riding: Some Notes on Ebonite.

FRIDAY, MARCH 28.

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS (at Middlesex Guildhall, Westminster), at 3.—Annual Meeting.

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (at King's College Hospital), at 4.30.—Clinical Meeting.

PHYSICAL SOCIETY (Annual General Meeting) (at Imperial College of Science), at 5.—Presentation of the Duddell Medal to Prof. A. A. Michelson.—At 5.45 (at City and Guilds Engineering College).—Exhibition of Research Work now in Progress.

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre jointly with Manchester Association of Engineers) (at Manchester), at 7.15.—J. Calderwood: Marine Diesel Installations with particular reference to Auxiliary Machinery.

JUNIOR INSTITUTION OF ENGINEERS (at Royal Society of Arts), at 7.30.—G. S. Taylor: Industrial Accidents: their Cause and Prevention (Gustave Canet Memorial Lecture).

ROYAL SOCIETY OF MEDICINE (Epidemiology Section), at 8.—Dr. W. Fletcher: Typhus-like Diseases of Unknown Etiology.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir Ernest Rutherford: The Transmutation of Matter.

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub-Centre).

SATURDAY, MARCH 29.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Nuclei and their Structure (4).

PUBLIC LECTURES.

SATURDAY, MARCH 22.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—M. A. Phillips: Pond Life.

SATURDAY, MARCH 29.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—I. E. Dallas: June Flowers in Alpine France.

Psychology and Industry

DURING the last fifty years there has developed a much closer association between scientific research and productive industry than was formerly the case, as is well known, many firms now have excellently equipped laboratories, staffed by highly qualified scientific men and technicians, devoting the whole of their time to devising improvements in the means of production and in the commodity produced These activities, however, are concerned primarily with the technical and mechanical aspects, hitherto much less attention has been paid to the human factor in industry and commerce It is very encouraging, therefore, to learn from the ninth annual report [1] of the National Institute of Industrial Psychology, just issued, that large employers of labour are now recognising to an ever increasing extent the value of the study of human 'behaviour' and 'endeavour', in relation to manufacturing processes and business organisation—that is, the application of psychology in the factory, workshop, and office

This appreciation is by no means confined to the employers who benefit by increased production The workpeople in the various establishments in which the Institute has conducted investigations have invariably extended their whole hearted co-operation in the experimental work, and acknowledged the variety of advantages—lessening of strain, irritation, worry and boredom, and increase of earnings, etc —derived from the adoption of the suggestions put forward by the industrial psychologist

Merely to state that the purpose of the Institute is the application of the principles of psychology and physiology in industry and commerce, is to indicate at once the variety of problems with which it is concerned and the wide field to be covered Members of the Institute's staff have been engaged in investigating the best methods of applying human energy in factories, offices, etc, especially in regard to the elimination of unnecessary movements, the most advantageous distribution of periods of rest and work, and the determination and realisation of other conditions which tend to the maximal health, comfort, and well-being of the worker They have also been concerned in the planning of the lay-out of plant, the co-ordination of processes in production, and the reduction of monotony There has been considerable develop-

[1] Obtainable from the Secretary to the Institute, Aldwych House, London, W C 2

ment in the application of suitable methods so as to secure more efficient and scientific selection of workers and enabling trustworthy guidance to be given to adolescents when choosing their life's work The educational activities of the Institute include the provision of training courses for managers, foremen, investigators, etc, lectures for employers and workers, and the publication of the facts established by its research work

The research work undertaken by the Institute, mainly by grants from the Rockefeller Trust, forms an important complement to the valuable researches carried out by the corresponding Government body, the Industrial Health Research Board, which is under the direction of the Medical Research Council The Institute's investigations in the field are of course largely dependent on the knowledge derived from such research

Industrial processes are so numerous, the conditions which obtain in factories, workshops, and commercial undertakings differ so much, and the types of workpeople and staffs are so varied, that only actual investigation in the establishments themselves can be expected to provide solutions to the many difficulties confronting the employers and the workers engaged in them The best evidence of the value of these investigations is that firms which have engaged the Institute's services have given 'repeat orders' for the extension of the work to other departments of their businesses Again, these investigations have been carried on in all kinds of industries, differing largely in their methods of organisation for production and distribution, but in all cases it has been possible, after a close examination of the situation by an expert in industrial psychology, to effect improvements in the conditions under which the operatives work or in the manufacturing processes and, generally, in both directions concurrently

In the safety razor blade department of a cutlery factory, the Institute's investigator recommended the installation of various mechanical devices to limit non-productive time (which in certain processes occupied as much as 53 per cent of the working period) and to minimise waste In 'piercing' alone, it was calculated that an annual saving of £200 would be effected on £2000 worth of material The improved organisation in the polishing and stropping shops led to increases in output of 78 per cent and 23 per cent respectively Rest pauses were introduced in the grinding shop with good results, and movement studies led to the devising of better working methods of grinding and polishing Also, suggestions were made for a new method of payment by progressive piece rates which would provide a more effective incentive to increased output

Among many other investigations carried out during the year, the report mentions a spinning mill in which such varied subjects as illumination, analysis of sales and organising production with the view of reducing costs of manufacture, and planning of work ahead were considered, a fancy goods factory where an annual saving of £1400 will be effected by the reorganisation of the gangs working the presses, and a railway service for which the lay-out of the iron foundry in the locomotive works was re planned, including the mechanisation of certain heavy operations resulting in the expenditure of less physical energy on the part of the workmen The report also gives interesting details of investigations into such varied businesses as a gas works, a chemical works, a number of radio manufactures, telephone and cable factories, textile machinery, a departmental store, engineering works, offices, and the General Post Office In all such investigations it not infrequently happens that the psychologist discovers factors which, although individually of apparently minor importance, have a cumulative detrimental effect upon the workers, with a consequential effect upon the nature and the amount of work performed

The need for assistance to a boy or girl in the choice of a career on leaving school is becoming more and more recognised, and in its vocational guidance and selection departments the Institute has conducted a large amount of research work and shown the definite value of psychological tests In 1922 it carried out a joint experiment with the Industrial Health Research Board In 1924 it began an experiment on a larger scale in the course of which the careers of 1200 London boys and girls have been closely examined Psychological tests were applied to 600, upon the results of which they were advised in the choice of an occupation, while the other 600 (regarded as a 'control' group) received the advice normally given by one of the Juvenile Advisory Committees of the Ministry of Labour

This experiment has been made possible by grants from the Carnegie United Kingdom Trusts, by the co-operation of the London County Council in enabling the tests to be carried out during the pupil's last term at school, and by the Ministry of Labour in the finding of suitable employment for the boys and girls after leaving school The completed results of this experiment are likely to

be published during this year, but the information already received indicates clearly that psychological examination with advice based upon scientific research must have in future a definite place in our system of vocational guidance and selection Other experiments of this nature with which the Institute is closely concerned are being conducted in conjunction with the Birmingham Education Committee and with the Fife Education Authority

This branch of the Institute's activity is not confined to school leavers Similar work has been successfully accomplished in connexion with higher administrative posts in businesses and in the selection of overseers, foremen, etc , in manufacturing establishments As a consequence of the introduction of these methods in a textile mill, the *total* labour turnover *due to dismissals* has fallen from 9 5 to 6 2 per cent since the adoption of the Institute's recommendations A large engineering firm reports that it has definitely proved that "the test gives us within an hour the measure of the boy's suitability which it would take three to six months to obtain in the works under the control of a foreman"

The Institute, of which the late Earl of Balfour was president until his death, is to be congratulated upon a very successful year of work—work of national importance which affects the community in a variety of ways, all tending towards the improvement of the conditions in which we work and live Its aim, like that of a hospital medical school, is to combine practice, training, and research The cost of the factory investigations of the Institute is met by the fees paid by the employers, but large numbers of applicants for vocational guidance must be turned away owing to their inability to pay for its expense Not only the vocational guidance work, but also the training and research sections of the Institute need endowment Indeed, as the Prime Minister recently said at the annual dinner of the Institute, "If you were endowed with something like a million a year, you could spend it in such a way that not a farthing of your endowment would be wasted" The Institute now possesses laboratories, research rooms, a library, and a lecture room It is performing services of unique national importance, welcomed by all classes of the nation It is appealing for an endowment fund of £100,000 in order to set its work on a permanent footing, and we cordially commend the appeal to trusts and generous benefactors desirous of promoting close contacts between the material and human factors of progressive life.

The Beginnings of Entomology.

Materialien zur Geschichte der Entomologie bis Linné Von Dr F S Bodenheimer Band 2 Pp vi + 486 + 4 Tafeln (Berlin W Junk, 1929) 2 vols , 100*s*

THE issue of the second volume of this important work has speedily followed the publication of the first (reviewed in NATURE for June 22, 1929) The present instalment, as exact and thorough in its treatment as its predecessor, gives evidence of immense industry on the part of the author, Dr F S Bodenheimer Continuing the subject of the study of insects during the seventeenth and eighteenth centuries, the volume before us opens with a section on applied or economic entomology, with especial reference to agriculture, sericulture, and bee keeping

The treatises on these departments that appeared from 1600 onwards were both numerous and bulky Besides precepts of some practical benefit, they were apt to contain a large quantity of valueless matter Much attention, however, was paid to the protection of orchard and garden produce from the ravages of caterpillars The migrations and depredations of locusts, more important to European husbandry in former days than at present, are noticed by the author at some length , much recent literature on the subject is quoted, and the recent researches of Uvarov are referred to with approval Interesting chronological tables are given of the occurrence of locust swarms in various countries of Europe Under the head of noxious insects, the author takes occasion to commend the remarkable observations of the Englishman, Robert Southall, recorded in his "Treatise on Buggs" (1730), and to regret that his remedial measures have not met with more recognition

An important section of the work is devoted to the subject of learned societies and academies To the influence of these institutions the author rightly attributes the wide diffusion of the spirit of inquiry which took its rise about the middle of the seventeenth century As those most deserving the attention of entomologists he enumerates the Royal Society of London, the Academy of Schweinfurth in Franconia, and the Paris Academy of Sciences The first named of these societies is, as the author truly declares, of more importance in the history of entomology than any of the continental associations But here, for once, we catch Dr Bodenheimer tripping Perhaps even an English reader might fail to recognise under the style of "Christophus Wien" the architect

of St Paul's Cathedral The misnomer is repeated on the same page, also in the index, and is accompanied by other orthographical curiosities of less importance Moreover, in the list that he gives of histories of the Royal Society, we look in vain for the monumental work of Bishop Sprat

Dr Bodenheimer does full justice, however, to the admirable performance of the Royal Society in realising and promoting from the outset the international character of natural science, a task in which it continued to lead the way for at least the first hundred years of its existence The *Philosophical Transactions* included from their first issue in 1665 entomological communications of considerable importance The first volume contains notices of silk and cochineal culture, as well as of insect plagues in America and the Ukraine On these speedily followed in later volumes the hitherto neglected work of Edmund King on the natural history and development of ants, physiological experiments on insects by Robert Boyle, Willughby's observations on the leaf cutter bee, and, what is perhaps especially noticeable, a list of 'inquiries and directions' for the guidance in entomological research of residents in foreign countries Much space is given by the author to the record of the early years of this Society, the efforts of which towards international co operation in the cause of science merit and receive his warm approbation

Excellent work from 1652 onward was produced by the members of the Schweinfurth Academy Among these were Muralto, Mentzel, Heister, and Loeber, whose researches dealt with the anatomy and life history of the mole cricket, dragon fly, breeze fly, and locust respectively A better-known name is that of Vallisnieri, who published in 1715 an illustrated account of the praying mantis with its portable egg packet

A remarkable item in the memoirs of the Paris Academy of Sciences is the first attempt at a natural classification of the Lepidoptera, based not only on the perfect insect, but also on the immature stages This was the work of Guettard, and dates from 1749

On the advent of journeys of exploration, there naturally followed an increasing knowledge of the forms of insect life The interest excited in this department tended rather, as in an earlier period of inquiry, to centre in the utilitarian aspect of the subject, in such insects, for example, as were serviceable in providing material for drugs or dyes, or, on the other hand, were capable of inflicting annoyance or damage, such as the dreaded 'jigger'

A genuine scientific spirit was shown by Marcgrave, who accumulated a large stock of entomological and other zoological observations in Brazil, unhappily, he died in 1644 at an early age At a later period, good natural history work was done in the West Indies by our countrymen Sir Hans Sloane, Griffith Hughes, and Patrick Browne, all of whom devoted a great part of their attention to entomology

In North America, also, the last half of the seventeenth and first of the eighteenth century produced many good observations on the insect fauna of that continent It is interesting to note that several of these saw the light under the auspices of the Royal Society, which association was, as we have seen, indefatigable in encouraging the researches of its correspondents, whether native or foreign, in all parts of the world In the eastern hemisphere, the same period was marked by the work of Hasselquist in Egypt, Syria, and Asia Minor, and of Adanson in Senegal, with a large number of other observant travellers In connexion with the new interest in geographical distribution, the subject of the dissemination of noxious insects attracted attention, and their introduction into European countries by human agency was dealt with by Osbeck, Kalm, and Bartholini On the gradual elucidation of the history of the cochineal and lac insects the author has much to say, the economic value of their products appealed strongly to the commercial spirit of the time

Curious evidence of the superstitious dread awakened by unusual and unexplained occurrences is afforded by the consternation that followed the supposed descent of insects in snow (Hungary, 1672), and the sudden appearance of swarms of a wood boring wasp (Prussia and Poland, 1679) The adaptation of insects to the changes of season, and the instincts that lead them to provide for their young, were dealt with, much on the lines afterwards developed by Paley, by William Derham, author of "Physico Theology", known also for his study on the death watch beetle, communicated to the Royal Society

A long list of popular works on entomology which appeared during the eighteenth century gives proof, says the author, that the foundation had been well laid for the great increase of interest in the study of insects which marks the following period Similar testimony is afforded by the formation of entomological collections, which, first started by Aldrovandi and Gesner early in the

seventeenth century, were continued on a large scale in the form both of private collections and public museums Among the latter a conspicuous place was taken by the British Museum, which soon after its foundation in 1753 acquired the extensive entomological collection of Petiver A photograph is given by the author of some of Petiver's Lepidoptera which are still preserved in the national collection Linnæus's own collection was acquired after his death by the Society which bears his name in London Both Oxford and Cambridge possessed large insect collections about the year 1750 In comparison with England, neither France nor Germany showed at this period much zeal in the formation of collections, Italy, however, established several museums in which entomology was to some extent represented

With the publication in 1758 of the tenth edition of his "Systema Naturæ", Linnæus may be truly said to have laid a secure foundation for systematic entomology The first edition (1735) made a fourfold division of insects into Coleoptera, Angioptera, Hemiptera, and Aptera By 1748, the date of the sixth edition, this division had been amplified, and in the tenth edition we find seven orders for the most part equivalent to those at present recognised The principal differences are that Linnæus's Coleoptera include the Orthoptera and Dermaptera, his Hemiptera include thrips, his Neuroptera have now been divided into five or more separate groups, his Aptera are also plainly heterogeneous The genera ranked by Linnæus under his orders correspond fairly closely with present day families But the greatest achievement of this tenth edition must be allowed to be the establishment of the binary system of nomenclature, which for the first time made exact identification possible

With a full, but not unduly copious estimate of the entomological work of Linnæus, Dr Bodenheimer brings the historical part of his book to a close There remains a carefully compiled series of tables in which is attempted an identification of all the species of insects mentioned by pre-Linnæan authors, from the Chinese writers onwards—a laborious task which few men, even with skilled assistance, would have had the courage to undertake But painstaking thoroughness is the mark of Dr Bodenheimer's enterprise from start to finish, and he has produced a work the value of which will be widely appreciated by all those whose tastes or avocations lead them to seek full and accurate information on the history of entomology

Our Nearest Living Relatives

The Great Apes a Study of Anthropoid Life By Prof Robert M Yerkes and Ada W Yerkes (Published on the Louis Stern Memorial Fund) Pp xix + 652 (New Haven Yale University Press, London Oxford University Press, 1929) 45s net

THIS stately book by Prof and Mrs Yerkes is an invaluable contribution to the study of the higher apes—gibbon, orang-utan, chimpanzee, and gorilla—and the historical part is so well done that it should never require elaboration The account of personal observations on chimpanzee and gorilla is not less valuable, but it will, of course, be added to and possibly modified by the authors and others In both functions of the book, the historical and the original, we recognise the critical acumen of the trained psychobiologist In the historical sections there is a rigorous and much-needed separation of the wheat from the chaff, the record of personal observations is a model of sceptical carefulness

We would say in general that this large and beautifully illustrated treatise is indispensable to those who would follow a line of investigation that has been characteristic of the last twenty years, the experimental and observational study of the higher apes It may be noticed that the gibbon and the siamang stand so much apart from the others, that Prof Yerkes would have omitted them altogether, which would have been a loss, had he been beginning his task afresh

The book begins with a general historical introduction, telling of man's ancient knowledge of the anthropoid apes, its extension during the Middle Ages, and its gradual improvement during the seventeenth and eighteenth centuries Thereafter a special part of the book is devoted to each of the four great types, and the method followed in each case may be indicated (1) structural peculiarities, species, and habitat, (2) mode of life in natural conditions, (3) life in captivity, (4) affective behaviour—for example, expression of emotions, words, temperament, (4) nervous system, sense organs, and receptivity in general, and (5) perceptual processes and intelligence The book ends with a comparative survey of the types and with a statement of conclusions The whole survey is characterised by lucidity, vivacity, and a mood of active scepticism In our judgment, the authors have steered their craft with shrewdness and courage between the Scylla of behaviourism and the Charybdis of anthropomorphism

Very interesting is the careful comparison between the four anthropoid types as regards external characters, habits, life-history, sociality, emotionality and expressivity, vocalisation (which never rises to language in the strict sense) and sensory receptivity The interest heightens when the authors come to the intelligence of apes, which they have no hesitation in rating high They compare the four types with one another, with monkeys, and with man as regards curiosity, imitation, parental instruction, attention, adaptivity, memory, imagination, instrumentation, and effective adaptation of environment The general result is to show that the orang utan, chimpanzee, and gorilla are mentally further from the monkeys and nearer to man than has been until recently believed

The book is a masterly piece of work, scholarly, careful, and non sensational, it shows a rare combination of scepticism with sympathy, and it ends appropriately by indicating the lines of further investigation that are at present most urgent and most promising

Medieval Maps

Reproductions of Early Manuscript Maps 1 *The Portolan Chart of Angellino de Dalorto, MCCCXXV, in the Collection of Prince Corsini at Florence* With a Note on the Surviving Charts and Atlases of the Fourteenth Century, by Arthur R Hinks Pp 12, with Chart in 4 Sheets, 24 in × 16½ in (London Royal Geographical Society 1929) 42*s* net

THE Royal Geographical Society has had placed at its disposal a fund for the reproduction of a series of selected manuscript maps, and the first issue of this series is the reproduction of the Portolan Chart of Angellino de Dalorto, which is in the collection of Prince Corsini at Florence The reproduction is to full size, and is in colour, the work was carried out by the Fratelli Alinari of Florence, by the difficult method of half tone colour plates—difficult, that is, for the registration of lettering and fine lines The result is successful, however, and the lettering is, considering the character of such old maps, fairly clear, though it must be confessed that the red names are clearer than the black It looks as if it would be desirable in future reproductions of this series to modify the process so far as concerns the black names A comparison might be made with the full-scale reproduction of the Bodleian Map of Great Britain (c A D 1300), which was carried out by the Ordnance Survey in 1870 The general appearance of this reproduction is not nearly so interesting as that of the Portolan Chart which we are discussing, but the brown names are easier to read than the black names on the chart

The original chart is drawn on a single sheepskin, about 42 inches in extreme length, and 26 inches in breadth The colours used were chiefly black, red, and green, but yellow, or gold, purple and brown were also used The outlines of the land are faint, but traceable in most parts of the map As is the custom with such charts, the face of it is covered by rhumb lines, in various colours, radiating from about twenty different points, from each of these points thirty two equally spaced, straight lines radiate There is also, drawn across the face of the chart, a system of rectangles, the lines going north and south, and east and west, spaced a few inches apart There is little or no fancy drawing, no fishes in the sea or monsters on land, though there are a few banners with arms, and the more important towns are marked by pictorial castles In fact, the chart is, in the main, a business chart, meant for use

The reproduction of the chart is accompanied by an admirable memoir by Mr A R Hinks, secretary of the Royal Geographical Society In this memoir Mr Hinks explains that he was charged by the Society with the duty of inspecting the principal fourteenth century maps now existing in the libraries of Europe, with the view of deciding which were most worth reproducing Of the eight Portolan charts of this century, or earlier, he was able to inspect seven, and chose the chart in question as being in the best style and in excellent condition, Prince Corsini readily gave his approval Mr Hinks adds brief, useful notes on the surviving Portolan charts, Catalan world maps and atlases of the fourteenth century

There may be a slight difference of opinion as to the exact date of the chart Mr Hinks, in his memoir, says, " the date [is] almost certainly 1325, though it has been read 1330 " The writer of this review took the reproduction to a scholar who is very familiar with fourteenth century Latin manuscripts, and this authority has little hesitation in reading 1330 The inscription then reads " Hoc opus fecit Angellinus de dalerto anno dni m ccc xxx de mense martii conposuit hoc "

As to the accuracy of the chart A series of cross-sea measurements, made by the writer of this review, from points easily identifiable, gave a mean scale of 75 miles to the inch for the north-east sheet of the reproduction, 84 miles to the inch for the

south-east sheet, 88 miles to the inch for the south west, and very variable numbers for the north west That sort of thing would be expected, for the north-west of Europe was relatively little known to Mediterranean sailors The mean scale of the better mapped region, that is the Mediterranean, Black Sea, and western coasts of Spain and Portugal, is about 80 miles to the inch, or a little less than one to five million An interesting feature is that there are four scales drawn for use in each of the four quarters of the chart These scales are identical, showing that it was intended that the scale should be the same all over the chart Each major division of the scale represents about 36 English miles, and each major division is divided into five minor divisions The outlines of Scandinavia, Denmark, and Scotland are very faulty, but the same remark would apply to our own Bodleian map, so far as concerns Scotland

The Bodleian map is about 46 inches long by 22 inches broad, on a single skin Its date is about A D 1300 The scale, in the better mapped portion (England), is, as nearly as may be, 1 1 million, or five times the scale of the Portolan chart The accuracy of this portion is very fair, and perhaps the map may serve to show the kind of material that was available in the better mapped regions when Angellino de Dalorto constructed his chart

With regard to the method of construction, the rectangular grid appears to represent north south and east west lines, and to that extent, as Mr Hinks remarks, the projection must tend towards a rough anticipation of Mercator But, as mentioned above, the scale is undoubtedly meant to be the same all over the chart, so that there was an attempt to combine conflicting conditions The main north south line bears symbols for north and for south and is so marked, the main east west line, at right angles to the former, bears symbols for east and west, and is so marked There can be no doubt about these two lines, and, perhaps, we may look upon them as the chief construction lines Perhaps, also, the various parts of the chart were fitted together in the manner of a jig saw puzzle, from more detailed maps, many of which no doubt existed As is usual with charts of this type, the Straits of Gibraltar are drawn considerably too far to the south, in comparison with the position of Alexandria, perhaps caused by a bending down of the western countries in the process of fitting

These matters, however, are questions of mere frame work The chart deserves to be studied in detail The names alone are full of interest, there is, for example, a wealth of place-names along the north coast of Africa As was to be expected, the interior topography of the continents depends largely on hearsay The Nile is made to rise a few hundred miles to the south of Tripoli, "hic surgit nil", and above the place where it rises is a legend to the effect that in that neighbourhood there dwell dragons, serpents, basilisks, and other horrible beasts

The anonymous benefactor, the Royal Geographical Society, and Mr Hinks, have given all those who care for ancient cartography an excellent reproduction of an important fourteenth century map, and geographers must welcome the success of this first issue of what promises to be a valuable series of reproductions of early manuscript maps

Our Bookshelf

History of the Natural History Society of Northumberland, Durham and Newcastle upon Tyne, 1829–1929 By T Russell Goddard Pp xvi + 195 + 12 plates (Newcastle upon Tyne Andrew Reid and Co, Ltd, 1929) 7s 6d net

THE Natural History Society of Northumberland, Durham, and Newcastle upon Tyne attained its centenary on Aug 19, 1929, and in order to commemorate the event the Council decided to publish a history of the Society and the Museum in which its collections are housed The work has been carried out with meticulous care by the curator, Mr T Russell Goddard, who is to be congratulated on the production of a volume which will prove to be of great interest not only to local naturalists, but also to the wider circle of those who find in natural history—in the words of Lord Grey—a sure recreation and a refreshing pleasure

The Society was founded by men who achieved permanent distinction, and many volumes of *Transactions* have been published since 1831, in which the fauna, flora, and geology of the two counties have been comprehensively dealt with The Museum is an imposing and dignified structure of classic design situated in spacious grounds It was John Hancock who made possible the erection of this beautiful building, which was completed and opened in 1884 Since 1891, a year after Hancock died, the museum has been known as the 'Hancock Museum' Among the collections, the Hancock collection of British birds is known to ornithologists throughout the world The Museum also contains the largest extant collection of drawings of birds by Thomas Bewick The Hutton collection of Carboniferous plants is of unrivalled value and contains seventy-nine type and figured specimens The geological department contains notable collections of Coal Measure fishes and amphibians, while the Permian collections, of both fishes and invertebrates, are the most extensive in Britain Some of the specimens in the ethnographical department are of interest as having been brought from Oceania by Capt Cook

The book contains brief accounts of these and other collections of unusual scientific interest,

together with lists of all the reference collections and of the new genera and species described in the *Transactions* Fourteen bibliographical sketches of the old worthies associated with the development of the Society form an attractive addition The membership of the Society has never been greater than it is at the present time, and though, like many other institutions that support museums, it has frequently been faced with grave financial difficulties, these have always been overcome, and a great tradition of public service and scientific responsibility has been developed

The book is well printed and beautifully illustrated, and is a worthy monument to the vitality of the Society and the industry of the author

Geologische Karte der Erde Von Franz Beyschlag Bearbeitet mit Unterstutzung durch die Preussische Geologische Landesanstalt 1 15,000,000 Lieferung 1, enthaltend die Blatter 1, 2, 3, 4 (Berlin Gebrüder Borntraeger, 1929) Subskriptionpreis der vollstandigen Karte, 150 g m

A satisfactory geological map of the world is of so much help that we turn with interest to the first four sheets of this map, which is being prepared for the Prussian Geological Survey by Prof Beyschlag and edited by Dr W Schriel The map will consist of twelve sheets The first section consists of the four northern sheets, which include Europe, northern Asia, and Canada, and the northern parts of the United States The scale is 1 15,000,000, so that the map gives only a general survey of the main geological divisions The colouring is clear and the primary geological structure is well shown The largest areas left blank in these sheets are in Mongolia and along the Amur Valley they are probably as well known as parts of north eastern Siberia, which are fully coloured

The map is difficult to judge without the colour sheet which is to be issued with the third part The sheets published have therefore to be interpreted by the symbols on a sheet entitled "Explanation previous for the first delivery of the Geological Map of the Globe" Some countries, such as Japan and Sicily, are shown in many colours but in small areas, the initial letters are seldom given in such cases, and without the explanation of the colours the age of the rocks has to be guessed

There are already good general geological maps both for Europe and North America, so that the sheets with the more difficult work are to come The map, however, promises to be very useful The table of formations suggests that the authors accept the existence of extensive areas of Palæozoic and Mesozoic metamorphic rocks

Selected Readings in Pathology from Hippocrates to Virchow Edited by Prof Esmond R Long Pp xiv + 305 + 26 plates (London Baillière, Tindall and Cox, 1929) 18s net

Prof Long, whose excellent "History of Pathology" was referred to in these columns last year (Nature, Oct 5, 1929, p 543), has again laid the student of medical history under his obligation by the present volume, which contains selections from important but, to many, almost inaccessible works from the dawn of scientific medicine down to the present time Antiquity is represented by Hippocrates, Galen, and Celsus, the Middle Ages by Paul of Ægina, Rhazes and William of Saliceto, the Renaissance by Antonio Benivieni, Fracastor, and Fernel, while the rest of the book contains passages from the leading British, French, Dutch, German, and American writers of the seventeenth, eighteenth, and nineteenth centuries, among whom British authors have a prominent place, as is shown by selections from Harvey, John Hunter, Baillie, Hodgson, Bright, Hodgkin, Corrigan, and Addison In the passages from French writers, who are represented by Fernel, Astruc, Corvisart, Laennec, Louis, and Cruveilhier, we miss the inclusion of selections from the works on diphtheria and typhoid fever by Bretonneau, who in the estimation of his countrymen comes only second to Laennec as a pathologist as well as a clinician

The selections from each writer are preceded by a short introduction giving an account of his significance in the history of pathology Prof Long himself has contributed the translations of the selections from the works of William of Saliceto, Antonio Benivieni, and Virchow The other translations include several contemporary versions, as in the case of Astruc, Morgagni, Corvisart, Andral, and Rokitansky

The text is interspersed with numerous portraits of the pathologists and illustrations from their works

Railway and Seaport Freight Movement with examples of British and American Practice By George Bulkeley Pp xiv + 222 (London Crosby Lockwood and Son, 1929) 28s net

Students of that department of transport which is specially associated with the transfer and handling of goods at ports between rail and ship will find Mr Bulkeley's manual an interesting and informative review of the conditions, written from the point of view of the man who is in charge of operations It is full of practical hints gleaned from a long experience in railway and dock work, and should prove a serviceable guide, particularly to beginners It is, in fact, designed as a textbook covering elementary principles, as well as being explanatory of the more complex features of port traffic organisation and operation

The author describes various modern types of freight rolling stock and freight shipping, with a consideration in the former case of motive power and service control The movement of traffic through shunting yards and sidings, to and from the quayside, is outlined and explained, and there is a description of various types of appliances for handling goods in and out of ships' holds Finally, the author discusses the subject of statistics in regard to freight movement and shows the value of a reliable system of records for guidance in operation The volume is profusely illustrated by photographs and diagrams, which form a useful adjunct to the text B C.

Letters to the Editor.

The Problem of Stellar Luminosity

I ASK your permission to reply to the arguments brought forward by Prof Milne (NATURE, Mar 22) against my treatment of the problem of stellar luminosity The outcome of my investigation is a formula which predicts the luminosity of a star of given mass and radius (or mass and effective temperature) I have followed the common procedure of first employing special assumptions to make the mathematical answer definite, and then removing the assumptions by calculating the effect of the greatest admissible variation from the conditions adopted as standard—thus obtaining what is equivalent to a probable error of the prediction The calculations of luminosity must, of course, be considered in conjunction with these estimates of probable error I think that the discussion in "Internal Constitution of the Stars" of all *known* sources of uncertainty is exhaustive, and I conclude that the error is not so great as to impair the practical value of the formula I have shown that differentially the result agrees excellently with observation, but absolutely it makes all the stars about ten times too bright In view of this remaining discordance I have been as eager as my critics in searching for possible loopholes or complications If Milne's scrutiny brought to light any new possibility I should be grateful, but his criticism is not of this type He claims that there is a fundamental inadequacy in my method, so that not even a rough value can be computed in this way

In my deduction I employ those laws and conclusions of pure physics which are generally accepted as trustworthy I think that most physicists will assent to my including among these the conclusion that matter in the usual stellar conditions of temperature and density behaves as a perfect (or slightly superperfect) gas—notwithstanding the doubts of my friend Sir James Jeans But there is one result that as yet ought only to be used tentatively, namely, the physical calculation giving the absorption coefficient or opacity of matter in stellar conditions If we accept it, my formulæ determine the luminosity, if we mistrust it, the application of my formulæ is inverted, and we use the observed luminosity to determine the intrinsic opacity of the material in the interior In the opening paragraph of his long *Monthly Notices R A S* paper, Milne proclaims his main conclusion that it is not possible to infer from the observed masses, luminosities, and temperatures the value of the absorption coefficient for the stellar interior, and in his letter to NATURE he puts the same challenge in the converse form, denying the dependence of luminosity on internal opacity

Now the greater part of Milne's letter is occupied with a problem which is only indirectly related to my investigation, namely, the problem of supplying energy (presumably from sub atomic sources) at a suitable rate to maintain the star in an approximately steady state for vast periods of time I think I was the first to insist on the difficulty of this regulation of supply (NATURE, Mar 21, 1925, p, 419, May 1, 1926, Supp) Many dilemmas similar to those touched on by Milne are collected and surveyed in "Internal Constitution of the Stars", Chap xi But these difficulties in reaching a satisfactory theory of evolution and in accounting, for example, for the Hertzsprung-Russell diagram, do not concern my investigation of luminosity, which depends only on the present equilibrium Milne complains that my scheme of equations does not automatically provide that $L = \int \epsilon dM$ shall be satisfied Of course, it does not As well might he demand that the equations by which the flow of water in a main is calculated from the head of pressure should automatically control the machinery of the pumps (It is not very clear whether in referring to contracting stars Milne takes ϵ to mean the actual rate of liberation of sub atomic energy or the rate from a fictitious distribution of sources which he introduces in a formulation of the cooling problem, with the latter meaning $L = \int \epsilon dM$ is automatically fulfilled without reference to my equations) My equations refer to ordinary equilibrium and they are indifferent as to whether the slow secular changes proceed with a time scale of a million or a thousand million years

Only at one point do considerations of evolution and energy supply impinge on my theory of stellar luminosity If fully known, they would enable us to assign an exact value to a certain factor (α in my formulæ, η in Milne's version), which depends on the relative distribution but not on the magnitude of the energy sources As it is, we leave this factor undetermined within limits, the extreme range is about $2\frac{1}{2}$ 1, and this is included in the uncertainty of prediction above mentioned Thus the one really vital sentence in Milne's letter is, "Similar considerations show that the luminosity of a star cannot be even roughly independent of the relative distribution of energy sources" That is to say, α and η have unrestricted range This throws over a conclusion on which Milne Jeans ('Astronomy and Cosmogony", p 101), and I had all reached agreement Instead of following up this assertion with the expected justification, he proceeds to argue that the luminosity depends on the radius (As this is what my formulæ assert, I have no need to dissent) It is strange that Milne should leave his most essential assertion unsupported both in his letter and in his longer paper It is strange that he should think it unnecessary to say why he rejects my calculation of the amount of dependence Strangest of all, he treats with equal contempt his own paper on "Stellar Equilibrium and the Influence of the Distribution of Energy production" (*Monthly Notices, R A S*, vol 87, p 708)

Finally, I can scarcely agree that Prof Milne has disproved my conclusion that the uranium model is unstable His objection is that physically a star cannot "contract indefinitely", sooner or later it must find a (contracted) configuration of equilibrium By the same argument Humpty Dumpty's position on the wall was not unstable, ultimately he found a new configuration of equilibrium A S EDDINGTON.

The Relation of Fluidity of Liquids to Temperature

NONE of the formulæ proposed for the effect of temperature upon the viscosity of liquids has secured general acceptance, in the sense of permitting satisfactory comparison of liquids

In the shearing over unit area defining viscous resistance, we may suppose at any moment an equilibrium between undeformed and deformed molecules, to which the Boltzman distribution function applies This leads to an expression relating fluidity to temperature of the form

$$\log \phi = -\frac{k}{T} + C,$$

where T is temperature absolute, and k and C are constants This expression can only be a first approximation, since it assumes k and C independent of temperature None the less, it was found to represent the relation of fluidity to temperature for every liquid so far tested—more than fifty—over a very wide range of temperature with an accuracy generally comparable with the experimental error Deviations become considerable as the temperature approaches the freezing-point

This result confirms Prof A W Porter's observation that $\log \phi$ plotted against $\log p$, where p is vapour pressure, gives a straight line, and specialises his deduction that some function of ϕ should have the form $f(\phi) = \frac{k}{T} + C$ (*Phil Mag* [vi], **23**, 458, 1912)

From the derivation from the distribution function, it appears that k, the slope of the line, should be a work function involving the specific heat of the liquid A simple work function which has given very interesting results is obtained as follows The observed specific heat C_p—mean value over temperature range—refers to unit mass Hence specific heat per unit volume is $C_p\delta$, where δ = density, mean value over temperature range The heat per molar area is obtained as $C_p \times (M\delta)^{2/3}$, where M is the formula molecular weight, that is, uncorrected for possible association or dissociation

It follows that to a first approximation, if k be the slope of the line $\log \phi \propto 1/T$, the expression $\frac{\text{Specific heat} \times (M\delta)^{2/3}}{k}$ should equal a constant K, the same for all normal liquids, while a relative indication of molecular association should be obtained as $a = \left(\frac{K}{K'}\right)^{3/2}$ for deviating liquids

The data available—principally the fundamental studies of Thorpe and Rodgers—give quite good confirmation of this relation For liquids which have been previously deduced to be 'normal' by other methods (cf W E S Turner, "Molecular Association" Longmans Green and Co) the values of the molar work function, in arbitrary units, ranged from 21 9 to 19 8 The values of the association factor a calculated for the abnormal liquids are generally of the right order of absolute magnitude, and place them in a relative order agreeing reasonably well with such orders as are obtained by other methods, it is admitted that these are somewhat discordant Thus the following values for a were obtained for typical cognate series of compounds

Substance	Formula	a
Water	H_2O	3 51
Methyl alcohol	CH_3 OH	2 70
Ethyl alcohol	C_2H_5 OH	3 15
Propyl alcohol	C_3H_7 OH	3 04
Butyl alcohol	C_4H_9 OH	2 95
Iso butyl alcohol	C_4H_9 OH	3 52
Formic acid	H COOH	2 66
Acetic acid	CH_3 COOH	1 64
Butyric acid	C_3H_7 COOH	1 35
Iso butyric acid	C_3H_7 COOH	1 66

Except for methyl alcohol, the trend of these values is regular and plausible The alcohols show a slow declination of association with increasing molecular weight, the fatty acids a more rapid one, while in both cases iso bodies show increased association compared with normal bodies

It is realised that the association factors found can be only relative, since the temperature variation is not allowed for It may be remarked that on considering modifications of the formulæ to include this variation, it was found that the published data on the variation with temperature of the specific heats of liquids appear to be very sparse and discordant

My thanks are due to Dr R C Houck for essential assistance in testing the formulæ suggested Should further applications give encouragement, a joint paper will be published in the *Journal of Rheology*

S E Sheppard

Research Laboratory,
Eastman Kodak Company,
Rochester, N Y,
Feb 3

Since my letter of Feb 3, a further search of the literature has shown that the specific form of Porter's function,

$$f(\phi) = -\frac{k}{T} + C, \text{ putting } f(\phi) = \log \phi,$$

has been used before The original application is by Señor J de Guzman, "Relación entre la Fluidez y el Calor de Fusion" (*Anales de la Sociedad Española de Fisica y Quimica*, 11, p 353, 1913) The author refers to a future article to be published jointly with Prof C Drucker, of Leipzig, in whose laboratory he was then working This article does not appear to have been published, so far as I can ascertain, but in an article, "Untersuchungen uber Fluidität" (*Zeit phys Chem*, 92, 287, 1918), Prof Drucker recapitulates and expands the application of the formula, used as an integration between temperatures T_1, T_2 of its differential form

$$\frac{d \log \phi}{dT} = \frac{w}{RT^2}$$

to deduce the work function w, which as previously stated by Señor de Guzman, is found to be nearly equal in many cases to the *molecular latent heat of fusion*

On the other hand, the form of the work function suggested in my letter above appears correct, to an equal degree of approximation Certain interesting consequences follow from this, with which I hope to deal more fully elsewhere

I shall not regret having unwittingly assumed some novelty in the specialisation of Porter's formula, if so doing should help to affirm and extend the previous work of the authors cited S E S

Feb 15

[When Dr Sheppard sent the above communication for publication, he was, of course, unaware that Prof Andrade had recently been giving attention to the relation between temperature and the viscosity of liquids, and had stated preliminary results of his investigations in Nature of Mar 1 Since that letter was published, we have received several others discussing some points raised in it, and we hope to include these in an early issue, together with Prof Andrade's remarks upon them —Editor, Nature]

The Age of Iron Meteorites

If meteorites are scattered portions of our solar system, derived from some disintegrated planet or from the earth, then their age cannot be greater than that of the solar system This is assumed to be about 3×10^9 years at the utmost If, however, meteorites come from other stars, it is possible that the period

of their solidification could date back some 10^{13} years A determination of the age of meteorites can therefore bear on the question of their source

Of the radioactive methods of age determination the lead method is here inapplicable , but Strutt's well known helium method is practicable if the sensitivity of the measurements be suitably increased In any event, it is essential not simply to heat the meteorite, but to bring it into complete solution A description of an apparatus, such as is required for the performance of this operation under absolutely air-free conditions, was given two years ago, together with some results obtained (*Zeits für Electrochemie*, **34**, 645 , 1928 , see also NATURE, **123**, 879 , 1929, as well as the communication of Dubey and Holmes (NATURE, **123**, 794 , 1929) concerning two helium measurements made in our laboratory)

At that time we confined ourselves to the determination of the helium content, and relied upon the meteorite analysis of other investigators for the radium values Owing to the fact that both measurements can vary somewhat in individual pieces of a meteorite, an element of uncertainty enters into the calculation In the course of our research we have, therefore, so far improved our method that in one and the same sample both the helium and the radium content are ascertained Our process of bringing the meteorite into solution remains essentially the same The helium so freed is now, however, measured by means of a resistance manometer developed from that designed by Pirani and Stern , with this 10^{-7} c c of helium can be determined with a 2 per cent accuracy (The limit of the qualitative test for helium by our method is of the order of 10^{-10} c c , see *Zeits phys Chem* , 134, 353 , 1928) The electrometric method employed for measuring the radium content permits an accuracy of about 10 per cent in measurements of 10^{-13} gm of radium All the reagents used in the solution process have been so freed from radium that their activity cannot occasion any error

In the following table the results of our work are briefly summarised In order to complete the series, we include four earlier determinations (in which we ascertained the helium, but other investigators the radium, value) , and also the helium values of six meteorites, of which the radium still remains to be measured These are added because the helium content is in itself of interest in the study of meteorites , it varies within very wide limits in meteorites of different source, and can therefore be used to test the common origin of fragments separately distributed on disintegration (See, for example, the agreement of helium values for the two masses of Mukerop and Löwenfluss) The only meteorite (Savik) in which both the helium and radium content is so abnormally low that we failed persistently to detect these elements qualitatively is also tabulated All the age values which were calculated from helium and radium content ascertained in the same sample are indicated by a star

It has generally been considered that the helium method gives only a minimum age estimate, on account of a possible helium leakage This objection cannot be raised in the case of iron meteorites (to which we have therefore confined ourselves for the present) because we have demonstrated that even red-hot metals are not penetrable by the smallest amount of helium , even after palladium had been allowed to glow for several hours, the quantity remained under 10^{-10} c c (see *Zeits phys Chem* (B), I, 253 , 1928) As further evidence we heated Mount Aylıff, the meteorite richest in helium, for twelve hours at 800° C , and ascertained that less than 5 per cent of helium was released This also explains why earlier workers who attempted to detect the helium content by mere heating found values far too low , Strutt found in Staunton Co less than 1 6 × 10^{-6} c c per gm , although it contains nearly twelve times that amount We do not believe, therefore, that our determinations of iron meteorites can be too low, owing to helium loss A possible thorium content (probably, however, too small to effect appreciably the calculation) would still somewhat reduce the age value

It will be noticed that some age values given in the table are higher than those found in any previous

application of the radioactive methods (The lead method gave a maximum of 1600 million years, the helium only of 570 million years) Although our iron meteorite results range up to 2900 million years, nevertheless not one is found to be older than the age of the earth The solidification date of all meteorites so far studied accords well, therefore, with the assumption that iron meteorites originate not from distant celestial bodies, but from our solar system

The Planet discovered at Lowell Observatory.

LAST week I indicated the basis of Lowell's prediction of an unknown planet exterior to Neptune Further consideration of Lowell's memoir leaves me of the opinion that the residuals in the motion of Uranus are too small for the orbit of a disturbing planet to be predicted with any certainty It may be of interest to give the opinion of Newcomb, who, with

his assistants, was responsible for the tables of all the major planets the positions of which are given in the *Nautical Almanac* In the introduction to his tables of Uranus he wrote "These tables of Uranus are based on elements derived from meridian observations of the planet from the time of its discovery by Herschel in 1781 to the opposition of 1898 The outstanding residuals between theory and observation, left in the solution of the equations, sometimes amount to one second of arc It is not possible at the present time to decide whether these differences are real or whether they arise from the errors of the ephemeris of comparison, which, between 1830 and 1872, was that derived from Bouvard's tables The observations since 1860 seem to be represented with great exactness" No great importance need be placed on the fact that Lowell used three normal places earlier than 1781 and that he included observations up to 1910 In justice to him, however, it should be stated that he made no claim to very great accuracy in the prediction

It is impossible to deny the existence of unknown exterior planets, but it appears to me quite unwarranted to jump to the conclusion that the newly found object is a major planet with a mass between that of the earth and Neptune It is not easy, on the other hand, to conjecture the nature of the body which for nearly two months has simulated in motion a planet distant more than 40 astronomical units If we imagine a body in opposition distant 49 units from the sun, moving in a circular orbit, its path would be parallel to the earth's path, but its speed only one seventh Consequently, it would appear to retrograde about 60″ a day After two months the earth's motion would be inclined at an angle of 60° to the direction of the planet and the apparent motion would be reduced to about half The question is, What sort of body other than an exterior planet would appear to move in this way? It is quite easy to answer that no permanent member of the solar system inside the orbit of Uranus could behave in this way The observations reveal that the object is distant If it were 25 units away, it would require to move at about half the earth's speed to appear nearly stationary at twice its distance But an object 25 units from the sun moving at half the speed of the earth would soon pass out of the solar system The inevitable conclusion seems to be that the body is either moving in an approximately circular orbit at the distance announced, or in a nearer orbit with parabolic or hyperbolic velocity and near perihelion

From all the information now available, the object is definitely a small planet, possibly comparable to the planet Mercury in size No known comet would appear so bright at so great a distance

From the newspaper reports it appears that the Lowell observers have spent a good deal of time during the past year in searching for the predicted planet, and that they have in the meantime discovered, as one would have expected, many minor planets which by their comparatively rapid motion have quickly shown their true character The new object, whatever its real nature, will be of importance, for if only a comet, it will be no ordinary one The comet which at present holds the record for greatest perihelion distance is 1927 *j*, which never approaches the sun nearer than 5 5 units and moves in an orbit which does not differ so very greatly from a circle The fact that, of the five known comets with greatest perihelion distance, four were discovered so recently as 1914, 1925, 1927 (two) is surely significant It looks as if long exposure photographs are revealing a number of faint objects inside the solar system which would otherwise remain unknown, and possibly we may soon have better knowledge from which to judge the distribution of comets in our system

With regard to comet 1927 *j*, it may be noted that the discoverers, Schwassmann and Wachmann, described it as of magnitude 13 to 14 with a well-defined nucleus and a circular coma about 2′ in diameter It appears not unreasonable to believe that the new object, which is described as of magnitude 15 to 16, is a still more distant object It is quite reasonable to expect that diligent search amongst the faintest objects we can photograph may reveal many faint comets at a great distance

The stumbling block in accepting the new object as the planet predicted by Lowell is its feeble luminosity Lowell stated that his planet would have "a visibility of the 12 13 magnitude according to albedo; and a disc of more than 1″ in diameter" The magnitudes reported vary from 15 to 16 0—the latter being on the international photographic scale A difference of three magnitudes in the brightness corresponds to a factor of 63 in the volume It is difficult to explain this by low albedo and high density, as the mass, if wrong by a factor of more than 2, would make the prediction meaningless The Lowell Observatory will in any case be congratulated on the discovery of what may be the most remote object ever observed in the solar system

A Method of Investigating Gas Exchanges of Living Tissues

Few, if any, really simple methods have been proposed for the simultaneous estimation of the carbon dioxide evolution and oxygen uptake of living tissues in which it is possible to maintain the composition of the gas mixture surrounding the tissue constant, and at the same time detect a rapid change in rates of gas exchanges The method outlined here has been found to be very simple, rapid, and trustworthy

The principle of the method is as follows a gas mixture circulates in a closed system over the material under investigation, and through a solution of barium hydroxide Since the carbon dioxide is thus absorbed, there is a reduction in volume of the gas mixture due to the absorption of oxygen by the tissue This causes the level of liquid to rise in a manometer placed between the closed respiration system and another closed volume of air (the compensator) The liquid is an electrolyte, and when it rises a small amount (about 1 mm), it makes contact with an electrode from which oxygen starts to be evolved, further decrease in volume of the system due to absorption of oxygen is thus prevented by this automatic electrolytic addition of oxygen which takes place at the same rate as that at which the oxygen is absorbed by the tissue

This rate is measured by measuring the current used in the course of the electrolysis by either finding the volume of hydrogen or weight of silver simultaneously set free

The rate of carbon dioxide emission of the tissue is found by observing the change in electrical resistance of the barium hydroxide solution, which rapidly increases owing to the conversion of the hydroxide into insoluble barium carbonate

It is essential that the platinum black electrodes should not remain long in contact with the baryta, more particularly while the gas stream is bubbling through it, as it is found that the barium carbonate

precipitate tends to form on any solid surface placed in the solution The electrodes thus become coated with barium carbonate and the 'cell constant' rises towards infinity This is readily prevented by a simple device the electrodes are kept in mercury at the base of the baryta tube in which the carbon dioxide is being absorbed When it is desired to estimate the quantity of carbon dioxide which has been absorbed, the gas stream is stopped and the mercury is lowered and the baryta comes in contact with the electrodes, the conductivity is measured, and the electrodes are again covered with the mercury and the gas stream is started again

The diagram of the apparatus is almost self explanatory Absorption of oxygen by the plants causes the solution in the manometer CD to rise into tube C, thus bringing the electrode c into electrolytic connexion

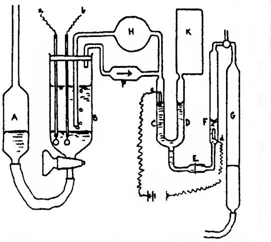

FIG 1 —A, tube for altering level of mercury in B B carbon dioxide absorption tube CD, manometer E, parchment membrane G, gas burette H, plant chamber K, compensator P, circulating pump Electrodes a and b are connected to a Wheatstone bridge

with d The parchment membrane E allows this movement of ions, but prevents changes in the gas pressure in the tube F from affecting the volume of the gas in the circulating system and compensator The gas burette G serves to estimate the hydrogen evolved simultaneously with the oxygen

The volume of the circulating gases fluctuates to an extent of about 0 07 c c on each side of the mean volume, and this defines the limit of accuracy with which the rate of oxygen intake can be estimated

The relationship between the resistance of the baryta and the quantity of carbon dioxide which it has absorbed is most conveniently obtained by calibrating the apparatus with known amounts of carbon dioxide The magnitude of the change in resistance for a given quantity of carbon dioxide increases as the process of absorption proceeds Using $N/20$ baryta, 1 mgm carbon dioxide brings about an increase in resistance of roughly 10 per cent

It is hoped that full details both of the calibration and 'rapidity of response' of the apparatus will shortly be published

It may be noted that the fact that the circulating gas system is closed throughout the course of the experiment makes this method particularly accurate, and useful when gas mixtures other than air are used in the investigation T A BENNET CLARK

Crossed Connexion of the Cerebral Hemispheres with the Muscles and Sense Organs.

I WISH to thank Dr Creed for his letter in NATURE of Mar 1 with its references

I am afraid that in my attempt to be brief I may have misled Dr Creed in one or two details I agree with him that the crossing of both afferent and efferent impulses seems a very clumsy arrangement, but my desire was to suggest a way in which this remarkable state of affairs might have been brought about

I did not mean to suggest that the median eye is the forerunner of the two lateral eyes In view of the number and variety of eye like structures in invertebrates, it seems that such organs can be easily developed, in fact, in *Sphenodon* there are two lateral eyes as well as a single median one The parapineal organ may be the remnant of the primitive median eye, and if so the well developed structure in *Sphenodon*, even if it is not functional, is worthy of investigation. Perhaps some comparative anatomist can throw light on this possible relationship I did not refer to *Sphenodon* previously because the crossed connexion occurs in fishes, hence the origin of that condition must have been in a more primitive organism If the pineal eye of *Sphenodon* does represent the same structure as the eye of an ascidian larva, it is curious that the organ seems to have nearly disappeared in fishes

I look upon the original crossing as efferent There is no need in the ascidian larva for an afferent crossing, as the optical images would be formed on the crossed side Where the crossing occurs and how many neurones are involved in the path to the muscles, I do not know, but in so far as the impulses are concerned with the production of movement they are efferent

When the crossed connexion had been established, the parts growing from that region would all be crossed and the afferent impulses would have to cross in order to link up with the efferent paths It is remarkable, however, that a new uncrossed system did not develop when lateral eyes became predominant As pointed out by Dr Creed, Ramón y Cajal's suggestion is out of harmony with the cortical distribution of the retinal areas in man

Indeterminacy in Physics

THE Principle of Indeterminacy in physics, to the history of which Sir Joseph Larmor has directed attention in NATURE of Mar 8, is sometimes referred to as though it might develop so as to dissolve all physical laws It is well to point out its limitations Its present phase is no more than the search among physical statements for their minimum content, rejecting repetition and superfluity From this point of view it is the necessary continuation of the chapter of upheaval of ideas introduced by Relativity, which dissolved so much

It is only by mathematics that superfluous statements, so subtle that they have hitherto evaded detection, can safely be analysed But mathematics is a closed chain of argument that reveals nothing that is not put into the chain originally, and physics, upon which it works, has been so far explored, that apart from detail, we know what it is going to say What it is going to say is, to attempt to describe the universe without Will or Purpose It does so, not because anyone believes that to be possible, but because those things are unmanageable by mathematics and have,

therefore, been left out expressly from the mathematical chain Hence whenever physics attempts an ultimate picture, the result is jejune, or absurd, according to the writer's taste In any case it is incredible "I had rather believe all the fables in the Legend, and the Talmud, and the Alcoran, than that this universal frame was without a mind"

Physics, having excluded purpose from its view, when it has no more to say, presents a scheme which is purposeless and therefore meaningless, both in its beginning and its end It is a self consistent scheme, but it is in no sense satisfying The conclusion to draw from it is, apparently, that we must try again upon a broader basis, little as we know how to do so In the meantime, all searches aimed at weeding out unjustified precision in our statements of natural 'law' fall into a class of lower importance, an exercise merely technical, interesting to those that are interested in that kind of thing

The Maladaptation of Trout Spermatozoa to Fresh Water.

A FEW years ago, when I was investigating sex ratio in trout, some facts came to light which I intended to pursue further, but as there seems no opportunity at the moment of doing so, I feel it is worth putting them on record Gray (*Jour Physiol*, **53**, 308, 1920) had already pointed out the remarkable fact that artificial insemination of trout eggs secured a much higher percentage of fertilised eggs than did natural fertilisation, and had shown that this was due to the extremely short time (1½ 2½ minutes) for which the sperm remain active

Struck by this observation, I made a few experiments with sperm in different solutions I need not go into details the salient point which emerged was that both sodium chloride and Ringer's solutions as well as somewhat diluted sea water enormously prolonged the sperms' period of activity Instead of about two minutes, it might run to ten or twenty minutes, and in sea water diluted with three parts of tap water, to half an hour or over Undiluted sea water was less favourable Details of optimum salt composition, osmotic pressure, hydrogen ion concentration, or of possible antagonistic salt action remain to be determined

The general fact emerges, however, that the trout is an animal which, though somatically fully adapted to fresh water life, is very imperfectly so adapted in its reproduction, its sperms being many times more efficient in a medium intermediate between its present and its ancestral environment

Curling

THE letter on the flight of a curling stone by Messrs Macaulay and Smith, in NATURE of Mar 15, seems to require a little filling out As an old curler, and one who has been much 'in the house', I may perhaps be pardoned for taking part in a subject the mathematics of which are above my head First, on good ice covered with ever so little frozen mist a stone 'borrows', bends, or curls far less than one passing over dry, clean ice, or very clean ice *just* on the thaw The amount of spin (handle) put on one stone without effecting the curl of that stone may be too great for another stone, and cause it to keep its original direction I have seen old stones, with the polish off them, take a lot of curl, even when played on the side with next to no cup My own view is a stone tends to turn on its outer edge and so to roll inwards, the spin of the stone when great reduces this outward turn, the tendency of the stone to follow the line of least resistance is slight, perhaps the 1 ft 11 in arrived at by Messrs Macaulay and Smith

Before leaving this interesting subject there is one more point worth consideration Should a stone be delivered with the weight of the body behind it, as from the hack, or is it more economical in energy to swing it, as from the crampit? The finest exponent of the game I have seen of late years does both, but his swing, if not followed by a forward slide of his body, every once in a while, causes him to 'drop' his stone If the flight is worth considering in one pair of dimensions, could some one give its correct line in the other?

Horse and Fowl Hæmoglobin

DURING the course of a spectrographic examination of horse and fowl hæmoglobin, we have noted that the absorption band having its peak at 4100 A for oxyhæmoglobin and 4300 A for hæmoglobin in solutions of the above compounds, does not appear when washed corpuscle suspensions containing hæmoglobin and oxyhæmoglobin in similar concentrations are examined Furthermore, the absorption which begins at 2500 A in solutions of horse hæmoglobin also is absent when hæmoglobin or oxyhæmoglobin is observed in washed cell suspensions The specific bands in the visible regions of solutions of the above pigments are observed in the washed cell suspensions in their usual location

Apparently there is, in the case of hæmoglobin in the cell, a possibility that it is in combination with some constituent of the corpuscle This problem is one of several concerning the blood pigment for which we are attempting to find a solution

An Anthropological Congress.

THROUGH the courtesy of a friend, I have had the opportunity of seeing a copy of a circular of invitation, dated Paris, Feb 15, 1930, to an anthropological congress described as *XV^e Congrès Internationale d'Anthropologie et d'Archéologie Préhistorique IV^e Session de l'Institut International d'Anthropologie Portugal, 1930* This invitation is signed by the president and secretaries of the Institut International d'Anthropologie, and is issued from its address in Paris Among the 'comité d'honneur' is one of the survivors of the 'permanent committee' of the *XIV^e Congrès International* (Geneva, 1912), another represents Switzerland on a "comité international de préparation scientifique des sessions", but there is no other apparent link with the older series of congresses

In view of the leading article on these congresses in NATURE of March 1, readers may be interested to have this further information

The Nobel Prizes for Research Work in Science

HISTORY OF FOUNDATION AND CONSTITUTION OF COMMITTEES

ALFRED BERNHARD NOBEL, engineer, chemist, inventor, industrialist, philanthropist, was born at Stockholm, Sweden, on Oct 21, 1833, he died at San Remo, Italy, on Dec 10, 1896, aged sixty three years The terms of his will, covering an immense capital sum, instituted an annual allocation of money prizes, of which the essential principle was their application for and towards the greatest benefit of mankind From inquiries which reach us from time to time, and from comments made upon awards of the prizes, it appears that the nature and work of the Foundation are not clearly and widely understood We think, therefore, that a useful purpose will be served by giving a sketch of Nobel's career and presenting in a compendious form, the main decisions and articles embodied in the Code of Statutes of the Nobel Foundation, which are recurrent in operation, so far as they are likely to concern scientific workers in the domains of physics, chemistry, physiology, and medicine

The story may appropriately begin with the discovery in 1846, by Ascanio Sobrero, of Turin, of nitro glycerine The process of manufacture was described in a communication to the Turin Academy of Sciences in February 1847, and therein Sobrero mentions its explosive properties In a lecture given about this date, before a scientific congress in Venice, he stated that "it is not yet possible to say anything as to the use that may one day be found for this liquid substance, which can be exploded by a shock, future experience alone will show us" Down to the early 'sixties, nitro-glycerine was regarded much in the aspect of a scientific curiosity, and its use as a powerful explosive was not contemplated The resourcefulness, patience, and inventive genius of Alfred Nobel wholly changed the situation

A recently issued English edition of "The Life of Alfred Nobel", by Prof H Schück and R Sohlman,[1] translated from the German edition of Dr Muelbe, supplies details of Nobel's first Swedish patent, and of those experiments and developments ensuing which revolutionised the technique of explosives Particulars will also be found there as to the manufacture of dynamite (1863), ballistite (1888), and other explosive materials

This "Life" is a welcome compilation, affording so far as possible an authentic account of Nobel's family history and upbringing, and of the activities which dominated his career Hitherto, details have appeared, more or less uncertain and incomplete But this issue bears the authority of the Nobel Institute, whilst the authors are specially qualified for their task Two forewords, by the late Dr Gustav Stresemann, and Sir Austen Chamberlain, respectively, are of interest in relation to the subject of international peace

[1] "The Life of Alfred Nobel" By H Schück and R Sohlman. Translated from the German of W H v d Muelbe by Brian and Beatrix Lunn Pp ix+353+18 plates (London William Heinemann, Ltd, 1929) 21s net.

It appears that owing to the reserve which was characteristic of Nobel, a biography of him could only be, in a sense, fragmentary, since extensive periods of his life's history remain as uncharted areas on a map In 1893 the University of Uppsala conferred upon him a doctorate of philosophy He furnished then a short autobiography, breaking silence, as follows "The undersigned was born on the 21st October 1833, he acquired his knowledge in private studies, and did not attend any secondary school He devoted himself particularly to applied chemistry, and discovered explosives known under the names of dynamite, and smokeless powder called ballistite and C 89 Since 1884 he has been a member of the Royal Swedish Academy of Science, and is also a member of the Royal Society (London)[2] and the Société des Ingénieurs Civils in Paris Since 1880 he has been a Knight of the Order of the Polar Star He is an officer of the Legion of Honour"

Although a Swede, whose alternative tongue was Russian, he wrote German, French, and English in faultless style To say that he seems never to have had leisure to live may appear paradoxical, nevertheless it has elements of truth Owning a native kindliness of heart, many deeds of sympathy with affliction sprang therefrom He was free from methods of dictatorship, and observed strict rectitude in business operations, and he held open and fair dealings with all in his employ

Nobel was conscious that his scientific discoveries, besides their technical and industrial applications, might have far-reaching overt implication Incidentally, he had placed in the hands of internationals ways and means for new destructive agencies amongst mankind in general The knowledge seems to have bred a haunting fear, and melancholy dread, intensified with passing years Peace between peoples became a subjective necessity of his being Possibly, after all, science and philosophy were in the middle distance only, and not in the foreground of his thoughts

"I have been wondering", he wrote (1892), "why the rules governing a duel between individuals should not be applied to a duel between peoples" Disarmament, he believed, could only be achieved by very slow degrees Somewhat later he had reached this conclusion "I am beginning to believe that the only true solution would be a convention under which all the governments would bind themselves to defend collectively any country that was attacked" His final will provided (through prize awards) for the promotion of friendly relations between the peoples, for the abolition or reduction of standing armies, and for the formation and increase of peace congresses

It is of interest to recall that on May 21, 1875, Nobel attended the Society of Arts in London, and read a paper "On Modern Blasting Agents", and it was announced as by the founder of the nitro-

[2] Dr Nobel was not a foreign member of the Royal Society of London

glycerine industry The chairman, Mr (afterwards Sir) Frederick Abel, advised the audience that the great experience of Mr Nobel, both from a practical and scientific point of view, entitled his views to very great consideration There, were, however, debatable points Abel summed up the discussion that took place at considerable length At the ensuing annual general meeting (June 30, 1875) Nobel was awarded the Society's silver medal for this paper Nobel had remarked that the foregoing was the only scientific memoir he had ever written He did not do himself justice in this respect Earlier, in 1865, he communicated a paper to the Paris Academy of Sciences, published with the following title "Résultats des expériences de sautage faits avec la nitro-glycérine, à la mine de la Vielle-Montagne" Also, in 1868, he attended the meeting at Norwich of the British Association and read a paper on "Dynamite, a Recent Preparation of Nitro glycerine, as a Blasting Agent" This was published in brief abstract

Nobel's comparatively early death was not unexpected From his earliest youth he had been delicate When only twenty he underwent treatment at a spa, oftentimes repeated Strenuous work and constant travelling from country to country naturally took their toll In 1893 he reached the age of sixty and heart trouble became more frequent From Paris he wrote, "It seems an irony of fate that they should be prescribing nitro-glycerine internally for me" and this to his sister-in law, Ludwig Nobel's wife "You are anchored in contentment I drift about without rudder or compass, a wreck on the sea of life, I have no memories to cheer me, no pleasant illusions of the future to comfort me"

The student of scientific biography will observe a curious parallel in the life story of Alfred Nobel and that of James Smithson, founder of the Smithsonian Institution, Washington, whose patrimony, though meagre by comparison, was designated (1826) for "the diffusion of knowledge among men" Each was unmarried, each of marked idealistic fibre Bodily infirmities were alike common Both careers came to a close in Italy, a land foreign to birth

By his own wish Alfred Nobel was buried at Stockholm in a grave in the northern churchyard where his parents and a brother had been interred Thus, the spirit of patriotism was preserved in the end

Design of Nobel's Will

It was provided in the will (drawn on Dec 27, 1895) that the interest on the capital sum available should be awarded annually in prizes to those persons who shall have contributed most materially to benefit mankind during the year immediately preceding Further, that the interest should be divided into five equal amounts

In the domain of science the appointments were three in number, specified as under

(a) One share to the person who shall have made the most important discovery or invention in the department of physics

(b) One share to the person who shall have made the most important chemical discovery or improvement.

(c) One share to the person who shall have made the most important discovery in the department of physiology or medicine

Further, the will stipulated that the prizes for physics and chemistry should be awarded by the Swedish Academy of Science, Stockholm, the prize for physiology or medicine by the Caroline Medical Institute, Stockholm "I declare it to be my express desire", wrote Nobel, "that, in the awarding of prizes, no consideration whatever be paid to the nationality of the candidates, that is to say, that the most deserving be awarded the prize, whether of Scandinavian origin or not"

The instructions of the will settled the form and scope of the Nobel Foundation, which was ushered into being in the year 1900, after prolonged deliberations The Royal Academy of Science, Stockholm (K Svenska Vetenskaps-Akademie) one of the two corporate bodies with whom is vested the adjudication of the three prizes in science, was founded in 1739 The functions of the Academy are to encourage the pursuit and the development of the sciences, and also to spread a knowledge of them through scientific papers and monographs The King is patron, and there are 100 Swedish and Norwegian members and 75 foreigners The Caroline Medical chirurgical Institute, Stockholm (K Karolinska Institutet) was founded in 1815 It corresponds to a university medical faculty, and has the same standing as the medical faculties at Uppsala and Lund

The Statutes of the Foundation provide that it is within the power of each corporation entitled to adjudicate prizes, to determine whether the prize or prizes it has to award might be granted to some institution or society

Nobel Committees

An elective Nobel Committee for each of the three scientific prize sections exists to promote the obligations devolving yearly upon the Stockholm institutions, consisting of three, four, or five members The committees receive and make suggestions respecting the grounds for allotments of prizes, whilst they have power to seek the aid of a specialist, if necessary, in furtherance of investigation To be qualified for election on a Nobel Committee it is not essential to be a Swedish subject

During the course of the month of September in each year the Nobel Committees are empowered to issue a circular to all those who are qualified, asking for nominations of candidates for prizes before the first day of February in the following year, such nominations to be supported by evidence, documentary and otherwise It is essential that only duly qualified persons propose candidates A direct application for a prize is not taken into consideration

1 *Physics and Chemistry Sections* The right to hand in the name of a candidate appertains to

(a) Home and foreign members of the Royal Academy of Science, Stockholm

(b) Members of the Nobel Committees of the Physical and Chemical Sections

(c) Men of science who have received a Nobel prize from the Academy

(d) Professors of the physical and chemical sciences of the Universities of Uppsala, Lund, Oslo, Copenhagen, and Helsingfors, at the Caroline Institute, Stockholm, and the Royal Technical College, Stockholm, and also those teachers of the same subjects who are on the permanent staff of the Stockholm University College

(e) Holders of similar chairs at other universities or university colleges, to the number of at least six, to be elected by the Academy of Science in the way most appropriate for the just representation of the various countries and their respective seats of learning

(f) Other men of science whom the Academy of Science may see fit to select

The members of the present Committee for Physics are—

Prof Carl W Oseen (Uppsala)
Prof V Carlheim Gyllensköld (Stockholm)
Prof Karl M G Siegbahn (Uppsala—Nobel prize, 1925)
Prof Henning B M Pleijel (Stockholm)
Prof Erik W Hulthén (Stockholm)

The members of the present Committee for Chemistry are—

Prof Henrik G Soderbaum (Stockholm)
Prof Theodor Svedberg (Uppsala—Nobel prize, 1926)
Prof Knut W Palmaer (Stockholm)
Prof Ludwig Ramberg (Uppsala)
Prof Hans Karl von Euler-Chelpin (Stockholm—Nobel prize, 1929)

Secretary to the above Committees—

Prof Arne Fredrik Westgren (Stockholm)

2 *Physiology and Medicine Section* The qualification for the right to nominate candidates is possessed by

(a) Members of the professorial staff, Caroline Institute, Stockholm

(b) Members of the medical class of the Royal Academy of Science, Stockholm

(c) Nobel prize-winners in the section

(d) Members of the medical faculties of the universities of Uppsala, Lund, Oslo, Copenhagen, and Helsingfors

(e) Members of at least six other medical faculties, to be selected by the staff of the Caroline Institute in the way most appropriate for the just representation of the various countries and their respective seats of learning

(f) Men of science whom the above staff may see fit to select

The Nobel Committee of the section shall hand in its verdict and proposals for the prize award to the professorial staff of the Caroline Institute within the month of September

The members of the present Committee for Physiology and Medicine are—

Prof Gunnar Hedrén (Stockholm)
Dr Hans Christian Jacobæus (Stockholm)
Dr Hans Valdemar Gertz (Stockholm)
Dr Einar Hammarsten (Stockholm)

Secretary to the Committee—

Dr Goran Liljestrand (Stockholm)

Special Funds of the Sections

The Statutes provide, within strictly defined limitations, for the establishment of Special Funds for each of the five sections of the Noble Foundation The proceeds of any and every such fund may be employed, subject to the approval of the adjudicators concerned, to promote the objects which the testator ultimately had in view in making his bequest, *in other ways than by means of prizes* In the domain of physical and chemical science, support in furtherance is consequently available, if judged to be of significance either in a scientific or a practical regard Proposals for the awarding of assistance of this nature remain with the respective Nobel Committees Similarly, such proceeds may be devoted to promoting research in medical science, and in rendering the results of that research of practical use to mankind In this section a proposition may be made by a member either of the staff of the Caroline Institute, or of the Nobel Committee

Obituary

THE RIGHT HON THE EARL OF BALFOUR, K G, O M, F R S

THE genuine statesman, so we read in the *Republic*, will be the man who, in contemplating the true good, makes it a pattern for ordering the State and individuals and his own conduct, who spends much of his time in philosophic reflection, and yet, when his turn comes, endures for the sake of the public welfare the toil of politics and ruling, not as though he were performing some meritorious deed but simply as a matter of duty In writing of the great personality lost to the nation on Mar 19 last, one can scarcely avoid recalling the well-known portraiture. For, if ever in the chequered course of human history Plato's ideal has been to some extent realised, it was in Lord Balfour's case Other political leaders have been classical scholars, men of letters, and even men of science Who, however, among Prime Ministers, has ever before not only made philosophy his main pursuit as an undergraduate, but also at the age of thirty published in a technical journal an elaborate criticism of the transcendental theory of knowledge of sufficient importance to elicit replies from such eminent Kantian scholars as Edward Caird and John Watson? And, needless to add, this was the outcome not merely of a passing phase in the career of a distinguished public man, it was the prelude to a large number of subsequent efforts in the field of speculative thinking, interest in which was no less keen in the man of eighty than in the man of thirty

Arthur Balfour came to Cambridge from Eton in

1866, and at once fell under the spell of Henry Sidgwick, his senior by about ten years Of Sidgwick it has been said "he did not teach as a prophet, and he required of his pupils hard thought, without promising them that this would result in any revelation of the secret of the universe", and Balfour himself wrote of him that "he never claimed authority, he never sought to impose his views, he never argued for victory, he never evaded an issue" That the pupil who was destined soon to become a warm personal friend was immensely influenced by his teacher there can be no doubt In all Balfour's published work, characterised, indeed, by an ease and beauty of style and a wealth of epigram to which Sidgwick's can lay no claim, there is to be traced that critical habit of mind, that evenly balanced judgment, and that distrust of dogmatic systematising which, in his undergraduate years, he had seen so uniquely exemplified In the year 1869, he took the Moral Sciences Tripos, one of the first to be examined under the new scheme, with the framing of which Sidgwick had been closely concerned

Ten years intervened between his taking the degree and the appearance in 1879 of Balfour's first book, "A Defence of Philosophic Doubt", although he had previously published several philosophical articles in *Mind* and elsewhere, and meanwhile he had entered the House of Commons as member for Hertford Fourteen more years elapsed before his second book, "The Foundations of Belief", saw the light in 1895, but, again, during the interval numerous articles of his had appeared in periodicals, amongst them a delightful essay on Berkeley, and two Lord Rector's addresses had been delivered, one at St Andrews in 1887, and the other at Glasgow in 1891 Then followed in 1915 the first volume of Gifford Lectures on "Theism and Humanism", delivered in Glasgow just prior to the outbreak of the War, and which he managed to prepare for the press before joining the Coalition Cabinet, and finally, in 1923, there appeared the further volume on "Theism and Thought", containing the second series of Glasgow lectures, delivered in 1922–23, when the author was more than seventy-four years of age Many smaller things ought to be mentioned, especially the striking presidential address to the British Association at the Cambridge meeting of 1904 It is an extraordinary record of independent and vigorous intellectual activity on the part of a man who was never free from the strenuous demands of political life, and was fulfilling various functions in the educational world and in many other spheres "Literary composition", he once said, "I have always found laborious and slow, even in favourable conditions" Yet whatever he wrote is remarkable for its fresh, lucid, and graceful mode of expression, as Sir Frederick Pollock put it in 1895, he will have done much to bring back the good days of Berkeley and Hume when philosophy could speak English.

At the time when Balfour's first book was written, the dominating philosophical influences in England, both at the universities and perhaps more decidedly among the philosophically minded outside the universities, were J S Mill and Herbert Spencer—Mill more than Spencer, although it is true that in Oxford and Glasgow German idealism had powerful representatives The philosophic doubt which Balfour defended was doubt as to the legitimacy of either of these ways of handling ultimate problems In dealing with the former, which had culminated in an agnosticism the cardinal tenet of which was that knowledge is confined to phenomena and the laws of phenomena, he directed attention not upon what was alleged to be unknowable but upon what was alleged to be known If we are to believe nothing but what we can prove, let us see, he urged, what it is that we *can* prove He started by emphasising as fundamental the distinction between the causes or antecedents which produce a belief and the grounds or reasons which justify one,—a distinction which every competent thinker would acknowledge as vital now, but which was constantly being lost sight of then Confining himself to logical grounds or reasons, Balfour tried to show, and certainly succeeded in showing, that, on the basis of an empirical theory such as was then current, the premises on which the system of modern science rests can neither be proved nor rendered even probable

A philosophy which is to justify the procedure of science must be prepared to give a coherent account of two radical beliefs at least—the belief in the uniformity of Nature and the belief in a world of physical things existing independently of the individual mind that is apprehensive of them, and of neither could the current empiricism give a coherent account As regards belief in an external world, Mill's doctrine of 'permanent possibilities of sensation' and Spencer's doctrine of 'transfigured realism' fell easy preys to Balfour's incisive dialect Neither could afford the slightest warrant for asserting the existence of a material universe the objects of which are composed of atoms and molecules, vibrating with different degrees of rapidity, and in which modes of energy are everywhere operative Spencer had himself admitted that if the theory of subjectivism were right the doctrine of evolution would be a dream, but the arguments which he brought to bear against what he called 'crude realism'—the "realism of the child and the rustic"—involved him in the very subjectivism he had attributed to the 'unimaginable blindness' of the 'metaphysicians' As regards the uniformity of Nature, Balfour argued that not only is the statement of it as an inference from particulars 'by simple enumeration' incapable of proof, but that, when so interpreted, it cannot be thrown into any accurate form save at the expense of making it unmeaning In dealing with transcendentalism, he maintained that, so far as causality is concerned, all that Kant, even on the most favourable view of his reasoning, can be said to have established is that the totality of phenomena at one instant is the effect of the totality of phenomena at the previous instant,—a general proposition which by itself is wholly inadequate to serve as a basis for scientific induction For this general proposition might be quite true, and yet the course of Nature might be,

to all intents and purposes, absolutely irregular, unless a fixed relation subsist not merely between the totality of phenomena but likewise between extremely small portions of that totality, and not merely between individual concrete phenomena but between classes of phenomena

The argument of the early work was, it is true, conducted with an *arrière pensée* in the shape of 'practical results' it was taken to yield, so far as a theistic view of the world is concerned But, in his second book, Balfour attempted to develop the negative speculations of philosophic doubt into a constructive, if provisional, system of thought As before, he proceeded by criticising what he here designates 'naturalism', meaning by that term virtually a purely mechanical theory of Nature, which "forces itself into the retinue of science", and "claims, as a kind of poor relation, to speak with her voice" With singular effectiveness, he sought to bring into the foreground the implications, in the spheres of ethics, æsthetics, and of rational thought generally, which this doctrine entails In the first place, the consciousness of freedom, the sense of responsibility, the authority of conscience,—these, along with the train of beliefs and sentiments from which virtuous deeds and generous ambitions spring, evince themselves as mere devices for securing certain competitive advantages in the struggle for existence In the second place, the persistent endeavours of æsthetic theory to show that the beautiful is a necessary and unchanging element in the general scheme of things indicate, at any rate, that mankind will not be easily reconciled to the view that beauty is but the chance occasion of a passing pleasure, and that, so far from disclosing hidden mysteries to us, poets and artists portray what, though it may be very agreeable, is seldom true and never important "We cannot willingly assent to a theory which makes a good composer only differ from a good cook in that he deals in more complicated relations, moves in a wider circle of associations, and arouses our feelings through a different sense" In the third place, human reason, so far from being Nature's final product, is, according to the doctrine in question, no more than one of many expedients for increasing our chance of survival, and which, we may suppose, will be gradually superseded by the growth of instincts or inherited habits, by which such adjustments between the organism and its environment as now seem dependent on it will be more successfully effected

Having thus exhibited the inherently irrational character of the naturalistic theory, Balfour attempted to sketch in outline a philosophic position which, while admittedly incomplete and suffering from gaps and rents, from loose ends and ragged edges, would yet do justice to the fact that in accepting science, as we all do, we are moved not merely by strictly logical considerations but also essentially by 'values' A fearless examination of the grounds on which judgments about the physical world are founded will disclose, he argued, that they rest on postulates about which it is equally impossible to say that we can theoretically regard them as self-evident, or practically treat them as doubtful We can neither prove them nor can we give them up Grant the same philosophic weight to values in those departments of speculation that look beyond the physical world, and naturalism will have to be abandoned once for all The vast majority of our beliefs, of our ethical, social, and religious beliefs especially, have not been attained by any process of logical reasoning, they have been generated in us by custom, education, public opinion, by the contagious convictions of countrymen, family, and so on, and, not least, by "the 'spirit of the age', producing a certain psychological 'atmosphere' or 'climate' favourable to the life of certain modes of belief, unfavourable, and even fatal, to the life of others" Unfortunately Balfour used the misleading and inappropriate term 'authority' by which to denote the group of influences thus enumerated But, as a discerning German critic has observed, what he really meant "may all be covered by the proposition that we men, in our higher spiritual life, are the products of history before we are its producers, and that in this double relation of ours to history the weight is permanently to be placed upon our dependence on the historical factors which surround and determine us" And it is, I take it, certain that, although he not seldom contrasted what he called 'authority' with reason, Balfour did not mean to imply that, in the last resort, the beliefs in question are 'irrational' On the contrary, he insisted that we are driven to believe in a supreme Reason, in order to account for the presence of these factors in the human world at all The presupposition that the world is "the work of a rational Being, who made *it* intelligible, and at the same time made *us*, in however feeble a fashion, able to understand it" is a presupposition "forced upon us by the single assumption that science is not an illusion"

I must not dwell upon Lord Balfour's further elaboration of these principles in the Gifford Lectures Those of us who have been privileged to take part with him in philosophical discussion need not to be reminded of his invariable fairness and patience in listening to views that were opposed to his own, or of his wonderful power of quickly seizing the main points in a complicated argument, and of freeing it from irrelevancies Nowhere will his presence be more sincerely missed than in the small gatherings of philosophic workers, where he was always so much at home

G DAWES HICKS

From Sir J J THOMSON, O M, F R S,
Master of Trinity College, Cambridge

IT may fairly be said of Lord Balfour that no statesman ever did so much to promote the development of science or kept in closer touch with its progress He was First Lord of the Treasury during the initial stages which led to the foundation of the National Physical Laboratory, and it was his sympathy and support which made the Laboratory possible He was instrumental in founding the Department of Scientific and Industrial Research,

and was, as Lord President of the Council, for many years its official head Everyone who has been connected with the Department knows the keen interest he took in its work and development and how much it owes to his advice and sympathy, on which they felt they could rely in any case of difficulty help was never given more gracefully or more tactfully The same is true of the Medical Research Council, in which he took deep interest

Lord Balfour was one of the pioneers in advocating the application of research to industry In the Sidgwick Memorial Lecture for 1908 he said of it "That on this we must rely for the improvement of the material conditions under which societies live is in my opinion obvious, though no one would conjecture it from a historic survey of political controversy" It was not only in industry that he recognised the importance of science, for in the same lecture he said "Science is the great instrument of social change, all the greater because its object is not change but knowledge, and its silent appropriation of this dominant function amid the din of political and religious strife is the most vital of all the revolutions which have marked the development of modern civilisation"

A liking and aptitude for science were in Lord Balfour's blood His uncle, the late Marquis of Salisbury, was distinguished among statesmen by his interest in science, and was president of the British Association at the famous meeting at Oxford when Lord Rayleigh and Sir William Ramsay announced the discovery of argon Lord Balfour's brother, Frank Balfour, before he was thirty, was the most distinguished morphologist in Great Britain, and his tragic death when he was but thirty one affected Cambridge more deeply than any event I can remember

Apart from his interest in science as a social and industrial force, Lord Balfour took a keen interest in it from the philosophical side and kept in close touch with modern developments He had been a fellow of the Royal Society since 1888 and had served twice on its Council, he was president of the British Association at the Cambridge meeting in 1904, and gave a very characteristic address which showed a close acquaintance with the new views about the nature of matter and was illuminated by witty and weighty criticisms of their philosophic aspect Conversation on scientific subjects with Lord Balfour was an intellectual tonic he was so quick in seizing the points, in picking out those which were vital, and in foreseeing possible developments

In 1919, Lord Balfour succeeded Lord Rayleigh as Chancellor of the University of Cambridge, and was most active and helpful in securing the means for the erection of a new library for the University, the most important event in its recent history He had previously been instrumental in securing a new professorship—the Arthur Balfour professorship of genetics A short paper he wrote in 1910 induced an anonymous benefactor to offer to found the professorship provided it was associated with the name of Arthur Balfour His connexion with Trinity College was long and intimate he had been a member of the College for sixty-four years and an honorary fellow for forty-two two brothers, Gerald and Frank, and two brothers-in-law, Lord Rayleigh and Henry Sidgwick, were fellows of the College and took an especially active part in its work, and the connexion, much prized by the College, has been continued in the younger generations of his family

---

From Sir Alfred Ewing, K C B, F R S, lately Principal and Vice Chancellor of the University of Edinburgh

I have been asked to write a note about Lord Balfour's association with universities, perhaps because I served under him as Vice-Chancellor in one of them for thirteen years Perhaps also because a previous service under him at the Admiralty, when he was First Lord during the War, had created a personal link which the subsequent intercourse maintained and strengthened Meeting Lord Balfour from time to time in the serene yet vigorous evening of his life, one found in him continually more and more to admire and revere and love

Lord Balfour's connexion with universities is too big a subject for a brief note He was Chancellor of two—Edinburgh for thirty nine years and Cambridge for eleven He was honorary doctor of at least sixteen, rector of two, a member of the senate of another He had been Gifford lecturer, Romanes lecturer, and so on Such points of established contact meant much to the universities concerned His immense influence and authority could be invoked, his advice could be sought, his sympathetic comprehension of university affairs never failed It was for such reasons that he undertook, in his double capacity as Chancellor of Cambridge and of Edinburgh, to lay the case for the universities before the Treasury, thereby securing a much-needed increase in the annual grants

To Balfour himself the academic atmosphere was congenial He was conspicuously a fine flower of university culture He understood the ways and aims of universities, their potentialities and their difficulties In many addresses he spoke of them with insight and affection He praised their past, noting especially how they had served as disinterested pioneers in scientific research He had confidence in their future But he was acutely alive to the need of adaptation to altering conditions He saw that the promotion of research had become a public duty, to be undertaken on a scale larger than they could handle and needing greater resources Fortunately, it fell to him, as Lord President of the Council, to direct the development of scientific and industrial research as a national task

Through his membership of Trinity, his brothers' fellowships there, the tenure of the Cavendish chair and, later, the Chancellorship by his brother-in-law, the late Lord Rayleigh, and the appointment of his sister, Mrs Sidgwick, to be head of Newnham, he had many ties with Cambridge When he was asked to become Chancellor, he had already for a long time held the like office at Edinburgh, and it was typical of his courtesy that before accepting the

Cambridge invitation he consulted Edinburgh opinion as to whether there might be objection to his holding both He was quickly reassured, and certainly neither University was prejudiced by his association with the other

With Edinburgh Balfour had a geographical connexion, for his ancestral home was not far off When in residence at Whittingehame, it was easy for him to come to us His visits were not infrequent, especially after the claims of political life had grown less insistent Some occasions were ceremonial, others more private, and these he unaffectedly enjoyed I recall his presiding when the Prince of Wales opened a new building and received an honorary degree The Prince, duly 'capped', was called upon to speak, and to the delight of a vast concourse of undergraduates proceeded thus to chaff the Chancellor

This is by no means the first time, Mr Chancellor, that we have met one another in circumstances such as these You will doubtless recall a day at Cambridge when you were good enough to confer a degree upon me in Latin, a language with which, I regret to say, I am unable to claim great familiarity Shortly afterwards I found myself in a position, as Chancellor of the University of Wales, to retaliate, when in admitting you to a degree at Cardiff it fell to my lot to address you at some length in Welsh Now, for the third time, with no handicap on one side or the other, we meet in a common tongue, and the match, if I may put it so, remains all square

Another notable occasion was the rectorial address of Mr Baldwin, then Prime Minister A bad tradition among Scottish students had made the address of the rector an opportunity for a 'rag' In pre-War days the Chancellor had suffered from this exuberance to an extent that strained even his good-nature When I asked him to come he stipulated that this time there should be reasonable order Accordingly I summoned the leaders of the students' unionist, liberal, and labour associations, the president of the athletic club, and one or two more, and showed them Lord Balfour's letter They declared with one voice that in his presence order must be and would be kept Sinking political differences they wrote a 'round robin' begging him to trust them and come He did, and was gratified to find them as good as their word The suppressive measures were their own, if drastic, they were completely successful It was the dawn of a new era

An example of a less formal visit was when Balfour came to talk to the students of history about the London Conference on Imperial Relations, and deftly countered an invited fire of questions Another was when he presided at the first of Prof Eddington's Gifford Lectures Such contacts were, I think, as agreeable to him as to us His greatness, his maturity, his detachment from the commonplace, were no bar to intercourse He would charm those he met into giving him of their best To some he would talk philosophy, to others music, to others medicine, to others the bewildering developments of modern physics There his bent towards science as well as philosophy found a double interest He rejoiced in the escape of scientific thought from the crude materialism which was vocal fifty years ago He followed the kaleidoscopic changes of atomic theory with an alertness that was the envy of younger men

My last meeting with him has left a happy memory It was on the day in July 1928 when, in honour of his eightieth birthday, he was entertained by the British Academy At the luncheon he had been in great form, clearly delighted with the tribute and moved by it That summer evening I met him again, sauntering hatless near his house, genial, buoyant, radiant It was hard to believe he had eighty years behind him Those whom the gods love die young of that company was Balfour

---

From SIR FRANK HEATH, G B E , K C B , formerly Secretary, Department of Scientific and Industrial Research

LORD BALFOUR was twice Lord President of the Council, first from October 1919 until the fall of the Coalition Government in October 1922, and again in 1925 on the death of Lord Curzon until the end of that Parliament in the spring of 1929 The Lord Presidency used to be considered a general utility office He converted it into a Ministry of Research The idea was not born in his fertile brain, for a Committee of the Privy Council for Scientific and Industrial Research and a similar Committee for Medical Research had been established during the War, and Lord Haldane's Committee on the Machinery of Government had recommended the creation of such a Ministry But Lord Balfour it was who turned an experiment which many thought destined to disappear with other War time devices into a reality which is now generally recognised as a permanent and essential part of modern government His unparalleled prestige in the political and intellectual worlds, his liberation from the rough-and-tumble of party politics, were favourable circumstances, but his abiding faith in the power of science to promote the happiness and well-being of man, his enthusiastic interest in the advance of knowledge, his sympathy with the scientific outlook and with young people, and his long experience of the way in which things have to be done in Great Britain, were the decisive factors

He was constantly called away during his first Lord Presidency by urgent Imperial affairs, to the Foreign Office when Lord Curzon was abroad, to Geneva in the first critical months of the League of Nations, to the United States for the first and so far the only international conference that has led to disarmament, but he found time in 1921 to lay the first foundations of a comprehensive structure destined ultimately to bring the whole national administration within the range of scientific influence He was chairman of a Cabinet committee appointed to study and report on the co ordination of the scientific work of all Government departments The need for economy had been the theme of discussion, and this was his way of meeting it Even to outline the findings of that Committee is impossible here, but it led to a gradual and decisive rationalisation of the research work done by the Admiralty, War

Office, and Air Ministry, of research for defence and for industry, of civilian and military research in medicine, of research in forestry and forest products, that has saved Great Britain untold expenditure and has brought an inestimable increase in efficiency

During his second term of office in a post once thought of as full of dignity and leisure, Lord Balfour devoted the larger part of his many-sided interests, and ungrudgingly of his time, to the continuance of this work He became chairman of the Medical Research Council and constantly attended the meetings of the Advisory Council for Scientific and Industrial Research, the bodies responsible for making recommendations to the Lord President as to the expenditure of the funds voted by Parliament for research in their respective fields He felt no embarrassment in this dual position, for the differentiation of function between the organs of scientific and administrative advice seemed to him natural and inevitable, provided they were properly integrated at the point of decision This integration the constitution of the two new departments of medical and industrial research had for the first time successfully achieved He always believed, and he hoped to the end, that a similar organisation for research in agriculture would complete the circle and so link together the services of science for the health and all the productive activities of man His chairmanship of the Research Committee of the Imperial Conference in 1926, followed by the Imperial Agricultural Research Conference in 1927 brought the realisation of this hope definitely nearer and led to most important advances in the co-ordination of agricultural research throughout the Empire

Lord Balfour realised, however, that the completed picture must include even more than this His first act on resuming office in 1925 was to consider a memorandum handed to him by Mr Baldwin, which led his critical, constructive, and experienced mind to formulate a plan for establishing on the lines of the Imperial Defence Committee—itself an earlier creation of his—a Cabinet Committee for Civil Research of which he was chairman until 1929 The object of this committee was to provide a permanent and flexible organisation which, by working through temporary sub-committees of experts specially appointed for the purpose, might study, and help the Government to solve, problems which crossed the bounds of single departments, or even those of England as a single member of the Imperial Commonwealth By this means co-ordination was secured in dealing either with general problems of organisation, or with specific questions such as sleeping sickness, the possibilities of geophysical survey, the scientific exploration of the Great Barrier Reef, or the restriction of rubber production The best brains within and outside Government departments were brought into council, without advertisement or the incubus of a published report, and incidentally the inevitable tendency to departmentalism was mitigated The present Government has altered the name of the committee and has added an Advisory Economic Council in more or less permanent session, with what results time alone will show, but Lord Balfour's plan will, it may be hoped, be understood and maintained

It is at first sight unexpected that a mind so detached as Lord Balfour's, so philosophic in its outlook, so critical and even sceptical in its methods, should have shown this constructive genius But if we remember, on one hand, the "Foundations of Belief" and on the other, the great Education Acts of 1902 and 1903, the riddle is plain His criticisms, often put as a question, forced his councils and his officers to think clearly, his sympathy with their hopes and difficulties won their devotion, his understanding of the scientific mind their confidence, his courage in decision when they sometimes hesitated to commit themselves their respectful admiration Often would he illuminate an intricate problem with a phrase which would simplify and clarify its complexities Such a phrase occurs in the preface he wrote to the classical study of moving loads on bridges, the outcome of four years' work by the Bridge Stress Committee of the Department of Scientific and Industrial Research "Fixed bridges and trains in motion become for brief periods parts of a single mechanical system" There stood the problem in crystalline clearness, and clear as crystal is the mind that has left us

---

By H T Tizard, F R S, Rector of Imperial College of Science and Technology, formerly Secretary of the Department of Scientific and Industrial Research

Lord Balfour held throughout his life a firm belief in the material as well as in the intellectual value of scientific knowledge He lived to see his views shared by most public men Largely through his influence, there has been brought about a complete change in the attitude of Parliament towards scientific matters, and the encouragement of research is now considered an essential duty of Government Lord Balfour gradually and inevitably became the man to whom his political colleagues, and many of his political opponents, naturally turned to keep them in touch with scientific developments It was remarkable how he managed to do it, busy man as he was It is hard enough for the scientific worker to keep abreast of modern progress, and one would have thought it almost impossible for a man so fully occupied with other affairs Lord Balfour succeeded partly by reading—one could usually find Nature and a modern scientific book on the little table by his chair—but mainly through meeting and talking to the leaders of scientific thought of the day, for whom he had a profound admiration

Lord Balfour took an intense interest in the Department of Scientific and Industrial Research, and found time to exert an inspiring influence on its work He never seemed to dictate policy or to interfere with executive matters he preferred to give the utmost freedom of action to his officers and to his distinguished Advisory Council, and yet, somehow, he dominated us all. If a new proposal was submitted to him he received it always with

interest, and often with enthusiasm He liked to talk about it, not to read about it, he found formal memoranda tedious! In conversation he would probe its weak points, and illuminate its good points, always sending one away with something more to think about, some fresh orientation of ideas

He felt doubtful about the wisdom of making grants to universities for specific researches, holding the principle that any grants given by the State to universities should be given for general purposes and not for specific objects He was more strongly opposed to the Department undertaking research at the cost of the State in the interests of particular manufacturing industries The argument that the particular industry was not doing enough, and that the work was necessary in the interests of the country, did not fundamentally appeal to him, for he held, broadly, that if British industry could not or would not adopt scientific methods, nothing that the State could do would save it This is not to say that he definitely refused to sanction such work, but he wished that whatever was done was limited in scale and was intended rather as an example of what might be, than as a substitute for what should be, undertaken by industry On the other hand, any research in the general interests of industry or of the community had his whole-hearted support, one might instance a comparatively recent development, namely, that of research into the cause and prevention of the pollution of rivers, as the kind of thing that interested him, and in which he thoroughly believed

In his somewhat infrequent visits to research stations—too infrequent for his and our liking—Lord Balfour's acuteness of observation often surprised me Those who knew him will probably think the word 'surprised' out of place I use it because, with my fairly extensive experience of distinguished visitors to research stations, I cannot recall anyone who excelled him in accuracy of appreciation and criticism after a single visit To his staff he was courtesy itself, and he was repaid by loyal and affectionate service Like all really great men, he treated them as equals need it be added that he knew how to get the best out of men ?

News and Views

THE Prince of Wales has promised to visit University College, Cardiff, on May 21, for the purpose of opening the new laboratories of physics and chemistry, which together form the north wing of the new buildings in Cathays Park, the civic centre of the city The group of public buildings in this quarter form an *ensemble* which is said to be unique in Great Britain To keep an honourable place in such an architectural constellation has taxed the resources of the College heavily, but the result of the effort has been duly gratifying Altogether, the cost of the new wing amounts to £220,000, of which some £15,000 is still outstanding It comprises laboratory accommodation of the most modern type and on a scale suitable to the needs of the large population of the district The Council of the College having recognised that advances in technology are essential to the welfare of South Wales and that such advances can only rest on a basis of research in physics and chemistry, these two departments were given priority in the programme of development The completion of this stage will, it is hoped, clear the way for further advances The Prince of Wales will also inspect the new Advisory Department of Agriculture, which forms an addition to the south side of the College buildings

WIDE interest is being taken in the forthcoming Wedgwood bicentenary celebrations which are to be held on May 19–24 at Stoke-on-Trent Their object is to commemorate the birth of Josiah Wedgwood (1730–1795), the great pioneer potter His systematic methods and scientific outlook were unique amongst the potters of his own day, and still command the highest respect The celebrations will be under the patronage of H M The Queen, whose sustained interest in the potteries and British pottery craftsmanship is well known, Princess Mary is to pay a visit to the Potteries during the celebrations A large influx of visitors is expected from all parts of the country and abroad, and the whole city will be in festive mood A historical pageant of eight episodes illustrating the history of the district from the days of the early Britons up to the modern industrial developments of the city will be produced daily by some 5000 performers reinforced by massed orchestras and choirs A military tattoo and torchlight spectacle, a tableau by 1500 pottery workers, physical training displays by 3000 school children, concerts, a fancy dress ball, and other items will cater for the interest and amusement of the general public

DURING the week of the Wedgwood celebrations the Ceramic Society, the object of which is the technical advancement of the pottery and other branches of the clay industries, will be the host of a large number of visitors representing kindred societies in Great Britain, the United States of America, Canada, France, Germany, Japan, Italy, Holland, Sweden, and Poland The Society and visitors will be received by the Lord Mayor and Lady Mayoress of Stoke-on Trent and entertained to luncheon Numerous other functions are also being arranged for the three days, May 21–23, set aside for the Society's celebrations These include a special visit to Wedgwood's works, when the party will be entertained to luncheon by Major Wedgwood, the present head of the works and a direct descendant of the great Josiah Wedgwood The Ceramic Society is also holding technical meetings, for which a large number of papers has been promised, and is offering prizes for the best essays on "The Contributions of Josiah Wedgwood to the Technical Side of the Pottery Industry" A special commemorative volume is also being published by the Society. Extensive exhibitions of modern

and historic pottery, amongst which will be certain pieces loaned by the Queen, will also be important features of the week

The Fifth International Botanical Congress is to be held at Cambridge on Aug 16–23 next In this connexion a circular has been issued on behalf of the Imperial Forestry Institute at Oxford, the Yale School of Forestry, and the Forest Products Research Laboratory, Princes Risborough, in which it is suggested that an informal conference on the systematic anatomy of wood should be conducted It is pointed out that this subject is rapidly increasing in importance, and more especially in the identification of timber "The numerous anatomical descriptions of timbers", state the authors of the circular, "which have been published of recent years, direct attention to the lack of any standard terminology, and it is thought that the Congress will provide a unique opportunity for discussing the possibility of introducing some measure of standardisation, at least among English-speaking people" There is little doubt on the subject of the confusion at present existing in this matter It will not be the first effort made to deal with it, but the present one has the advantage of being better planned It is also hoped to arrange a scheme for the exchange of material among botanists and forest botanists who are willing to undertake the study of a family or group Finally, the authors of the circular state that they are desirous of obtaining the views and co-operation of as many as possible of those who are interested in this subject They therefore invite suggestions of matter for discussion both from botanists who propose to attend the Congress and from those who will be unable to do so The suggested conference, should it receive adequate support, may be expected to achieve results of real practical importance to the forester, botanist, and timber merchant

The Royal Society for the Protection of Birds has issued an appeal for £4000 to purchase the site of a proposed permanent sanctuary for wild fowl in Romney Marsh A nucleus of eighteen acres has been in the hands of the Society for some time, and there is now an opportunity of completing the scheme The site consists of grassland, reed beds, mud banks, and open water it is far from roads and is made still more inaccessible by wide intersecting ditches The description suggests that the place is an exceedingly favourable one for the protection of the bird visitors, particularly ducks and waders, for which this part of Kent is well known The scheme has novelty for Great Britain in that the sanctuary will probably be more important as a reserve for wintering birds and resting migrants than as a breeding haunt That there is need of such reserves was shown by the report of the international conference on the protection of migratory wild fowl, held in London in 1927, and it is much to be hoped that the present proposal will be well supported

The Symons Memorial Lecture for 1930 of the Royal Meteorological Society was delivered on Mar 19 by Dr Herbert Lapworth, who took as his subject "Meteorology and Water Supply". Dr Lapworth dealt mainly with the story of the rain between its precipitation as rainfall on the surface of the ground and its later appearance in the form of streams, springs, and underground water, that is to say, a brief outline of the sciences of hydrology and hydrogeology as bearing upon the preliminary investigation of the water engineer Precision in water-supply problems can only be obtained by the collection of data in these two sciences and in rainfall statistics Water-engineers start from the basis of rainfall, the laws of fluctuation of which are regarded as more precise than the laws of hydrology and hydrogeology The preliminary investigations of water supply, however, are based upon nineteenth century rainfall observations, whereas there is good evidence that in the previous century there were longer and worse droughts than those which occurred within the next hundred years If such conditions recurred probably no waterworks in Britain could adequately meet them After discussing the driest years, on which basis waterworks were designed, Dr Lapworth dealt with floods and stream flow in general, reviewing the relation between rainfall and run off and the losses due to evaporation and other causes in streams and underground water The movement of underground water, the formation of springs, and the fluctuation of water level were described, and references made to bournes and disappearing streams The question of wells and the effects of pumping were discussed and the artesian basins of the world were briefly noted, illustrating the immense distances travelled by underground water

In his Friday evening discourse on Mar 21 at the Royal Institution on "Sea Birds and Seals", Mr Seton Gordon described the seals and birds found on the Atlantic coast of Britain The gannet is the largest and strongest flier of British sea birds In summer, from August until the second week in October, they are to be seen passing north and east, past Rudha Hunish, the most northerly point of the Isle of Skye Most of the gannets may be seen later on flying back to St Kilda This is ninety miles west of Skye, and is their nearest nesting haunt to that island, so these gannets make (including the double flight) a journey of 200 miles each time they fish on the coast of Skye A gannet has a great aversion to land Thus all the gannets of St Kilda which fish in the Minch towards its northern part all make for the Sound of Harris opening When they fly homeward, heavy laden with fish, they fly only a few inches above the sea; in large parties the numbers are almost always uneven It is a remarkable thing that the gannets find their way home to St Kilda through mist and fog, often when there is a strong side wind blowing The stormy petrel is smallest of British sea birds, it is only 6 inches long It was named petrel or 'peter el' (little peter) because it was believed that, like Saint Peter, it was able to walk upon the water The stormy petrel is a nocturnal bird That is why sailors count it unlucky to see a stormy petrel in daylight It is only on very dark days (and dark days usually presage a storm) that the stormy petrel is abroad, on fine days it sleeps at

sea Mr Seton Gordon also showed a film of the Atlantic seal, probably the first which has been taken of these animals on their island In October all the Atlantic seals of a wide district go to a lonely isolated isle where they have their young There may be 200 young seals on one of these islands For the first six weeks young Atlantic seals are land animals, during all this time they do not enter the water of their own accord

AT their meeting on Mar 22, the Trustees of the British Museum approved the purchase for the Department of Zoology of the very extensive and valuable collection of skeletons of mammals, birds, reptiles, and fishes formed by the late Mr E T Newton A particularly valuable section is Mr Newton's series of the otoliths or ear bones of fishes, these are often the only remains of fishes found in a fossil condition, and the collection has frequently enabled geologists to determine remains that would otherwise have been quite unrecognisable The collection will be available for study and research only Recent acquisitions in the Department of Geology include British fossils bequeathed by the late Mr G W Young, and others purchased from the collection of the late Mr E T Newton, the most important of the latter are a series of Pliocene mollusca from the St Erth beds, Cornwall These beds are two small patches remarkable for being the only known English beds of Pliocene age lying west of Kent and East Anglia The fossils occur in clay underlying sand and gravel, and unless this clay is opened up for some special reason, the fossils are unobtainable H M the King has placed on loan in the Department of Botany 267 specimens of dried plants from Nepal The collection is of special value in the Museum because of the lack of material from Nepal, only a very small area of which has been explored botanically The large and valuable herbarium of the late Mr C E Salmon has been bequeathed to the Department Mr Salmon was an authority on certain genera and on the distribution of British plants, and at his death he had almost completed a flora of Surrey The European Herbarium has been further enriched by the purchase of the herbarium of the late A A do Carvalho Monteiro This consists of about 4500 sheets and provides a good series of Portuguese plants

THE importance of the medical and surgical applications of electricity can scarcely be overestimated If we assume that the importance of any sphere of activity is reflected in the literature which arises regarding it, then Great Britain is very backward compared with other countries In Germany there are seven journals exclusively devoted to radiology, in the United States six, in France five, in Italy four, and in Britain one In a paper read to the Institution of Electrical Engineers on Mar 20, Dr Leggett pointed out that medical research would greatly benefit by an improved engineering finish being given to electro-medical apparatus Much of this comes from abroad, where there is a large home demand for it Foreign manufacturers are, therefore, in a better position to supply cheap apparatus than the British manufacturer who has to compete with them There are firms for manufacturing medical apparatus in the United States, Germany, and France which, individually, are larger than the whole British industry for this class of goods put together Since the late Mr Campbell Swinton first used X ray tubes in Great Britain, revolutionary improvements in their manufacture have taken place Although the electron tube has many advantages, yet, as until recently its price was nearly £40, it is little used Its price is now £25, but as in Germany one can be purchased for £9 there is a great scope for reduction in price It is gratifying to find that England has taken the foremost place in protective measures against the disease which attacked many of the early operators They form the basis of the international protective measures adopted at Stockholm in 1928

MR CHARLES HASKINS TOWNSEND, Director of the New York Aquarium, has published a most interesting account of his aquarium and the management of aquaria in general ("The Public Aquarium its Construction, Equipment, and Management" Department of Commerce, Bureau of Fisheries, Appendix 7 to the Report of the U S Commission of Fisheries for 1928 Bureau of Fisheries Document No 1045 Washington, 1928) The New York Aquarium is very spacious and is able to keep under specially favourable conditions marine mammals and some of the larger fishes in addition to the smaller fishes and invertebrates usually to be found in the tanks In the large floor pools there are porpoises and various seals One unusually active Californian sea lion has lived nineteen years in the aquarium Even manatees, which are difficult because of their sluggish habit have lived there as long as seventeen months and two years respectively, a Jew fish of 200 pounds weight has been kept more than ten years, and smaller fishes such as the gar (*Lepidosteus*), mudfish (*Amia*), and striped bass (*Roccus*) for more than twenty four years Results are very good also in the smaller tanks and aquaria, and various exhibits, including fish hatching, are on view This very useful document includes not only the description of building and setting up of aquaria large and small with details of lighting, heating, water, and air supply and all other essentials, but also describes in detail the methods of collecting and transport of the various creatures, their general management, food, diseases and their treatment, together with the approximate cost of construction and upkeep The paper is illustrated by photographic figures showing apparatus and many of the aquarium animals

DR A C GOODINGS, a graduate of the University of Leeds, has been appointed to an important post under the Ontario Research Foundation on the recommendation of Dr S G Barker, of the British Research Association for the Woollen and Worsted Industries Dr Goodings, after taking first class honours in chemistry, entered the Department of Textile Industries with a Clothworkers' scholarship, and, working under Prof A F Barker and Mr J B Speakman, proceeded to the degree of Ph.D through textiles, and later took the post graduate diploma in textiles Dr Goodings'

studies have covered a wide field, including the chlorination of wool and other problems During the past session, as a Clothworkers' fellow, he has been engaged on research into the fundamental principles underlying worsted drawing and spinning

The Ninth International Horticultural Congress will be held in London on Aug 7–15 The papers to be presented will be divided into three main groups (1) Propagation, (2) pomology, and (3) botanical gardens and general subjects Many countries on the continent of Europe, including Russia, will be represented, and several papers are promised by distinguished American workers Particulars of the Congress and of the excursions which will follow it can be obtained from the secretary of the Royal Horticultural Society, Vincent Square, London, S W 1, at the invitation of which the gathering is being held

A preliminary notification has been issued of the twenty fourth International Congress of Americanists to be held in Hamburg on Sept 7–13, 1930 Questions of general import will be discussed by the Congress as a whole, but sectional meetings will also be held for papers dealing specifically with the aboriginal peoples of America and their ethnic relations, the prehistory of America, manners and customs of the various groups of Indians and their distribution in the Old and New World, the aboriginal languages, the discovery and colonisation of America, and the geography and geology of America, with special reference to human activities The subject of one general session will be the civilisation of the Indians at the time of their first contact with Europeans and to day, which will be opened by a report by Prof Sapper, of Wurzburg The arrangements for the Congress are in the hands of an organising committee, of which the chairman is Prof G Thilenius and the secretary Dr R Grossman Subscriptions should be sent to "Internationalister Kongress", c/o M M Warburg and Co, Bankers, Hamburg

Sterilised surgical catgut has been added to the schedule to the Therapeutic Substances Act, 1925, as being a substance the purity of which cannot be adequately tested by chemical means (*Statutory Rules and Orders*, 1930, No 26 H M Stationery Office Price 1*d*) Before sale of sterilised catgut, manufacturers must test, or have tested by a recognised institution, samples for the presence of living bacteria, and full directions are given of the procedure to be ollowed in carrying out this test

The annual 'Medical Directory' guide to British spas and marine health resorts, now entitled, "The Waters and Coasts of Britain", by Dr Fortescue Fox, has recently been issued (Messrs J and A Churchill, 40 Gloucester Place, W 1 1*s* net) Information is given respecting the situation, climate, and other features of the principal health resorts in the British Isles, together with the characters of their waters, if any, and the medical indications for their use Lists of hotels, hydros, and other residential accommodation are also included

The new Belfast Museum and Art Gallery has not been long in showing that it means to adopt the most up to date methods in educational propaganda A very attractive programme of Wednesday night lectures has been announced, and these and the exhibition of natural history and industrial films on Saturdays, have attracted audiences which crowd the lecture hall Naturalists' field clubs in Ulster are alive to the value of the Museum, and are gradually extending their membership and their activities

The issue for December 1929 of *Terrestrial Magnetism and Atmospheric Electricity* contains a portrait and brief obituary and appreciation of Dr J P Ault, commander of the non magnetic ship *Carnegie*, who lost his life in the destruction of the ship by an explosion at Apia on Nov 29 last A further list is given of the ocean magnetic results obtained on this seventh and last cruise of the *Carnegie*, the list relates to the period from June 25 to Sept 23, 1929, when the ship arrived at Honolulu

We are glad to find that *The Aquarist and Pond Keeper* is prospering It has already increased by four pages, and this year it is being published every alternate month instead of quarterly The winter number (No 8, vol 3, 1929) contains an interesting article on the breeding of the angel fish *Pterophyllum scalare* by the Rev Bertram Stower This is the first time that the angel fish has bred in Great Britain, and it has never been known to breed in captivity in such numbers It is estimated that three hundred young from the broods were alive in the pond at the age of three months The parents were still guarding their young, although some of them showed a certain amount of independence

The transactions of the Prague meeting, in September 1927, of the Section of Terrestrial Magnetism and Electricity of the International Union for Geodesy and Geophysics, appeared under date June 1929, at the close of last year, as *Bulletin* No 7 (pp 269 + xii) of the Section On account of the illness of Dr L A Bauer, secretary of the Section up to the close of the meeting, and now president, the bulletin was prepared by Dr J Fleming on his behalf, and has been printed under the care of Dr Ch Maurain, the present secretary It comprises the proceedings and minutes of the meetings (pp 54), special reports (pp 30), reports of national committees (pp 92), comments on the agenda, and various scientific communications (pp 80), and official information (pp 12)

Applications are invited for the following appointments, on or before the dates mentioned —Graduate assistants in mechanical engineering and electrical engineering at the Rutherford Technical College, Newcastle upon Tyne—The Director of Education, Northumberland Road, Newcastle upon Tyne (April 4) A temporary lecturer in civil engineering in University College, Rangoon — The Secretary to the High Commissioner for India, General Department, India House, Aldwych, W C 2 (April 5) A responsible teacher in the Engineering Department (Mechanical and Electrical Engineering), and a teacher of electrical engineering, at the Oldham Municipal Technical College

—The Secretary for Education, Education Offices, Oldham (April 10) An assistant master for mathematics and science at the Westcliff Day Technical and Commercial School—The Headmaster, Dav Technical and Commercial School, Fairfax Drive, Westcliff on Sea (April 11) A pathologist and an assistant pathologist in the Pathological Department of the Royal Northern Hospital—The Secretary, Royal Northern Hospital, Holloway Road, N 7 (April 12) Six temporary marketing investigators under the Ministry of Agriculture and Fisheries, for investigations into methods of agricultural marketing organisation — The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (April 14) A director of the Bristol Municipal Museum and Art Gallery—The Town Clerk, Council House, Bristol (April 30) An assistant professor of biochemistry in the University of Alberta—The Secretary of the Board of Governors, University of Alberta, Edmonton, Canada (May 15) A professor of chemistry in the University College of North Wales—The Registrar, University College of North Wales, Bangor (May 24) A male temporary junior assistant metallurgist or metallurgical chemist under the Directorate of Metallurgical Research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18 A lecturer in mathematics and physics at the Dudley Training College for Teachers—The Secretary to the Dudley Training College Council, Education Offices, Dudley A physicist under the Linen Industry Research Association, for work on applications of physical and colloid science to textile finishing processes—The Secretary, Research Institute, Lambeg, co Antrim An assistant pathologist in the Public Health Department of the Shanghai Municipal Council—J Pook and Co, 68 Fenchurch Street, E C 3 Two women B Scs at the Wellcome Physiological Research Laboratories for, respectively, biochemistry or chemistry and for the bacteriological department—The Director, Wellcome Physiological Research Laboratories, Langley Court, Beckenham

Our Astronomical Column

The Trans-Neptunian Planet — The following observations of position have been received those of Mar 12 and 17 were given only to the nearest second of time in R A

	U T	R A	N Decl	Place	Observer
Mar	12 125	$7^h\ 15^m\ 49\ 6^s \pm$	° ′ ″	Flagstaff	
	17 049	7 15 41 ±	22 7 18	Yerkes	van Biesbroeck
	19 0206	7 15 39 86	22 7 38	Königstuhl	Wolf
	21 0333	7 15 35 00	22 7 47	Neu Babelsberg	Struve

The planet is now approaching the stationary point, which it will reach about the end of March On the assumption of circular motion with radius 45 units, opposition would have taken place about Jan 9 4 U T, the longitude then being 108° 26 5′, and south latitude 12′ or 13′

Prof Shapley reports that the brightness has been measured at Harvard Observatory the magnitude is 16 0 (*Morning Post*, Mar 22) From its faintness it appears that the planet is not larger than the earth, and that its albedo is very low Dr Struve (who called the body a comet) gave the magnitude as 15 3

In all probability the mass is considerably below Lowell's estimate of 6½ times the earth's, in this case, it would be largely a matter of good fortune that his predicted longitude was so near the truth It is, however, just possible that a planet covered with liquefied gases would have a very low albedo, in which case its diameter might exceed the earth's

Comets.—Comet discoveries are coming in quick succession, and we are already assured of four perihelion passages in 1930, apart from the possible detection of the periodic comets D'Arrest and Tempel (2) Comet 1930 c was discovered by Mr Wilk, of Cracow Observatory It is his second discovery within three months The following positions have been received from the I A U Bureau

	U T	R A	N Decl	Observer	Place
Mar	$21^d\ 18^h\ 38\ 0^m$	$1^h\ 31^m\ 2^s$	18° 26′ ″	Wilk	Cracow
	22 19 46 7	1 29 21 2	19 55 11	Struve	Neu Babelsberg

Struve gave the magnitude as 5 9, so the comet should be an easy object in a small telescope The deduced daily motion is -97^s, N 85′, which would give R A $1^h\ 18^m$, N Decl 29° 50′ on the evening of Mar 29, about 7° south-east of β Andromedæ

The following elliptical orbits have been computed for Beyer's comet, 1927 *b* The equinox is 1930 0

T	1930 Apr 21 64 U T	1930 Apr 28 5760
ω	26° 27′	29° 54′ 53 4″
Ω	116 33	116 53 12 7
i	71 17	70 5 47 4
log q	0 3120	0 301150
Period	640 6 years	91 503 years
	Computer, Mr Bower and Miss Moore Observations, Jan 23, Feb 18 Mar 14	Dr C H Smiley Feb 19 Mar 2 13

The comet is a good deal fainter than Wilk's, but is approaching perihelion, and is visible with moderate instruments The following ephemeris is for 0^h U T (*I A U Circ* 258)

	R A	N Decl
Mar 29	$6^h\ 9^m\ 9^s$	39° 11′
Apr 2	6 11 42	40 32
6	6 14 52	41 49
10	6 18 36	43 3

Mr F E Seagrave finds a period of 20,000 years for Wilk's earlier comet, 1929 *d* This should only be taken to imply that there is very little deviation from parabolic motion

Observatory at Bedford College, London — The completion of a fresh wing at the Bedford College for Women (University of London) has made possible the erection of a small observatory on the roof of the new building The Woolwich Arsenal Institution, acting on the advice of the Astronomer Royal, generously handed over to the College a seven inch refracting telescope by Grubb, which had been at the Institution since 1872, and which it is now hoped will enter on a new sphere of usefulness The Astronomer Royal performed the opening ceremony on Mar 17, the chair being taken by Prof H H Turner Sir Frank Dyson gave an address on "Everyday Astronomy", in which he pointed out how little is known of astronomy from a practical point of view, even by educated people interested in the theoretical side, and indicated how the simpler phenomena may be studied by comparatively simple observations leading up to the more detailed observations which the telescope makes possible.

Research Items.

Systematic Studies of Mammals.—Mammalogy, in the curiously restricted sense in which Gerrit S. Miller uses the term in his review of the progress of this branch of zoology (*Smithsonian Report for 1928*, p. 391, 1929), concerns itself primarily with the systematic study of mammals. The advance which has been made in the cataloguing and classifying of the world's mammals is very striking. In 1758, Linnæus knew only 86 mammals, a century later Baird knew 220 kinds in North America alone, and now in the same limited portion of the earth's surface about 2500 forms are recognised. Especially since 1890 progress has been rapid, and this, strange to say, has to do with the invention of the break-back pattern of mouse-trap, which has played an invaluable part in bringing into the study the smaller denizens of woods and fields. In the 'nineties Trouessart's "Catalogus Mammalium" enumerated 4423 species; since his last volume appeared in 1898, not less than 8700 new names have been added to the list of living species and sub-species, and the process is continuing at an undiminished rate of about 250 a year. This and the general development of systematics is interesting and important, but mammalogy means more than this, and we wish that the author could have found space to refer to the great development which has taken place also in the study of the mammal as a living organism, for it is the biological trail that promises to lead furthest into the unknown.

Zebra-Horse Crosses.—In 1902, Cossar Ewart described successful crosses made between horses and Burchell's zebra. Afterwards in America the ass was successfully crossed with Grevy's zebra, which is larger and more docile, but matings with the horse failed. Mr. Elmer Roberts (*Jour. of Heredity*, vol. 20, No. 12) describes crosses since made in Indiana between a male *Equus grevyi* and thirty mares, beginning in 1912. Eight colts in all were reared. They were all chocolate coloured with black stripes, although the dams were of different colours, bay, black, and gray. Three of the colts were male and five female, but all were sterile. These zebroid hybrids were gentle and intelligent, somewhat smaller than horses, but beautiful in appearance. They were good workers, and were better able than horses to withstand high temperatures. Being easily trained, they would appear to be valuable as domestic animals, and in certain respects preferable to mules.

Japanese and Chinese Fishes.—Mr. Henry W. Flower has gathered together a large number of notes and records of fishes chiefly obtained from the markets of Japan, Shanghai, and Hong Kong ("Notes on Japanese and Chinese Fishes", *Proceedings of the Academy of Natural Sciences of Philadelphia*, vol. 81, 1929). Among those from Shanghai is a new species of barbus, *Barbus nigripinnis*, which the author places in the new sub-genus *Glabrobarbus*, differing from *Hemibarbus* in the presence of two barbels which are maxillary, and a very short snout, the dorsal spine being long and smooth. The lower fins are very dark, giving the fish a characteristic appearance. Most of the fishes listed are from Hong Kong, upwards of 180 species being recorded.

Collembola of Ireland.—In *Proceedings of the Royal Irish Academy*, Vol. 39, 39B11, January 1930, Mr. H. Womersley contributes a useful list of the Collembola of Ireland, adding 17 species to the 50 kinds already known from that country. His paper commends itself to all students of these obscure insects, since he provides diagnostic keys to the families, genera, and species of all the British forms. No comprehensive work on the latter is available at the present time, and Mr. Womersley's paper supplies a means for their identification once the student has familiarised himself with the structure of a few leading types and is able to dispense with the use of illustrations. Out of a total of more than 700 described species of the order, 153 are here listed as British. The need for a monograph on the group is becoming increasingly evident as Lubbock's well-known volume is now completely out of date. Collectors and observers of these insects are few and far between and even to-day there must be still a number of British species awaiting discovery.

Duration of Life in *Drosophila*.—Considerable quantitative studies have now been made on the influence of various environmental conditions on the length of life in *Drosophila*. It has been found that low temperature, ventilation, and alcohol prolong the duration of life in these flies, while various degrees of starvation with or without water shorten it. Mr. W. W. Alpatov (*Amer. Naturalist*, January 1930) has studied the effect of different kinds of feeding of the larval and imaginal stages on the life of the fly. In one experiment, small flies were produced by removing the larvæ from food before the normal end of larval feeding, but there was no effect on their longevity. It was already known that flies grown at low temperature were larger. Small flies can also be produced by growing them at high temperature, but the duration of life is different from that of the small flies produced by under-feeding. In other experiments, flies were kept on synthetic food with or without yeast. The absence of the yeast greatly reduces the length of life of both males and females. From earlier work of Pearl, it is concluded that the relation between temperature and duration of life is represented by a simple exponential curve, while the relation between starvation and duration of life follows the upper part of a logistic curve.

Mycorrhiza in the Ericaceae.—Prof. Knudson, of Cornell University, and Dr. Rayner discuss again this oft-debated question in the *New Phytologist*, Vol. 28, No. 5, December 1929. Prof. Knudson is of the opinion that he has grown *Calluna vulgaris* from seed, after sterilisation with calcium hypochlorite, and obtained perfectly healthy seedlings under sterile conditions. He is aware that Dr. Rayner has previously failed to do this, and argues that her sterilisation methods (with mercuric chloride) were so drastic that the seedlings never grew thoroughly healthily, and also suggests that injection with the fungus symbiont just tipped the balance in favour of growth, by its effect upon the residual mercuric chloride left on the seed coat from the washing operations. Dr. Rayner, however, argues that Prof. Knudson's grounds for regarding his seedlings as completely sterile are far from convincing, and that his subsequent methods of examining these seedlings would leave the hyphæ of the symbiont still undetected. Under the conditions of his experiment, the hyphal complexes in the host cells, characteristic of fully developed mycorrhizal infection, were not to be expected, the fineness of the normal mycelium necessitates a special technique for its detection.

Floods of the Seine.—The floods that periodically threaten Paris are due to the coincidence of sudden thaw and heavy rainfall in the east and south-east of the Paris basin. The result is that the Seine is unable to carry away the water quickly enough. Many

preventive measures have been suggested In *Matériaux pour l'Étude des Calamités*, 4, No 20, Dr E Joukowsky proposes a new solution of the problem by the boring of absorbent pits establishing com munication between the surface water and the subsoil This would result both in storage and in drainage The pits would be in river beds in order to save waste of land and preferably at river junctions They would be dug at some distance from any artesian well The value of the wells or pits would clearly depend on their number, diameter, and depths, and to decide these questions a careful study of the level of ground water and the absorption power of the soil would be required

Formation of Limestone - Most great limestone formations of past geological ages have had an origin independent of coral reefs, and were apparently laid down in relatively shallow seas Many were alter nately above water, with resultant sun cracking, and submerged, with marks of wave action On the Great Bahama Bank such conditions of deposition occur to day Waste of terrigenous origin is absent, and there are no coral reefs Yet a white chalky mud known as drewite is being deposited In the March number of *Discovery*, Mr M Black gives some account of a preliminary investigation of this deposit by an American expedition in which he took part Needle shaped crystals of aragonite and grains of calcium carbonate compose 90 per cent of drewite The re mainder is sponge spicules, tests of foraminifera, etc Hard lumps among the soft ooze proved to be com posed of crystalline calcite enclosing rather more foraminifera than ordinary drewite This recalls the recrystallisation of ancient limestones known as pseudo breccias The second recrystallisation by which the whole mass, and not merely the lumps, be come solid is still obscure, but it is probable that the cementation takes place when the aragonite needles are converted into calcite This, however, would appear to take place only in the layers that are buried, since the aragonite is comparatively stable in contact with sea water Further investigations are promised

***K* Absorption Edge of Zinc** —In their communica tion on "The Fine Structure of X Ray Absorption Edges", in NATURE of Oct 26, 1929, p 652, Prof D Coster and M Wolf remark that although they have had no difficulty in observing several secondary edges in the K absorption spectra of copper, they were unable to observe fine structure in the case of zinc Mr Suekichi Kawata, of the Physical Institute, Kyoto Imperial University, informs us in a letter dated Jan 25 that he has obtained three secondary edges with zinc in the zincblende used as an analysing crystal employ ing the method of Lindsay and others (G A Lindsay and G D Van Dyke, *Phys Rev*, 28, 1926, J C Nuttal, *Phys Rev*, 31, 1928) The energy differences relative to the main edge are (in ν/R) 12 3, 8 0 and 3 3, which may be the right order of magnitude of the energies of $M_{IV\ V}$, $M_{II\ III}$ and M_I of zinc or the next higher element gallium respectively The details of the photogram will not reproduce satisfactorily, but we submitted it to Prof Coster, who writes "I have seen the photo graph of the K-absorption edge of zinc obtained with the zinc of zincblende as analysing crystal It seems possible that Mr Kawata has really got a fine structure of this edge If this is true, the question which re mains to be solved is, whether there is an essential difference between the intensity of this fine structure in the case of zinc and that of copper as was supposed in the letter of Coster and Wolf (NATURE, Oct 26, 1929) or not Experiments are in progress at Gronin gen to try to settle this question"

Capture of Electrons by α-Particles —The first February number of the *Physical Review* contains further details of the experiments of A H Barnes on the capture of electrons by α particles In a pre liminary report published last year (see NATURE, Sept 7, 1929, vol 124, p 389), it had been claimed that capture occurred only when the relative velocity of the electron and α particle was the same as the speed of an electron in one of the inner Bohr orbits of singly ionised helium, or when the two particles were relatively at rest A similar result is now reported for the capture of two electrons to give a neutral atom of helium, and the form of apparatus which has been used is described This consists of an evacuated tube, holding an incandescent plate as a source of electrons, with a set of auxiliary electrodes to give the electrons any desired speed, and to determine their paths To avoid contamination, the α particles enter the tube through a thin glass window, and after passing through the cloud of electrons are sorted magnetically and detected by the method of scintillations, the zinc sulphide screens being set up either inside or outside the tube The total number of scintillations which have been counted is more than 7×10^5 Mr Barnes's results seem to show that electron capture takes place in less than 3×10^{-10} sec in a region where the electron density is probably not greater than 10^7 per c c

Prevention of Corrosion in Lead Buildings —*Bulletin* 6 and *Technical Paper* 8 of the Building Research branch of the Department of Scientific and Industrial Research (H M Stationery Office) deal with the above subject They are drawn up by Mr F L Brady and deal with the subject in a way likely to be of service to builders and architects

Mine Rescue Apparatus —We have received *Paper* No 47 of the Safety in Mines Research Board, which deals with a type of gas mask evolved by the Board on the basis of experiments by Dr S H Katz (of the U S Bureau of Mines), who has been working at Sheffield under a scheme of exchange of skilled in vestigators, and Mr C S W Grice (London H M Stationery Office, 9*d* net) The mask is of the hopcalite type, employing a specially prepared mixture of manganese dioxide and copper oxide which converts carbon monoxide into carbon dioxide The type of mask successfully used in the United States, known as the 'All Service' mask, has been improved so as to show appreciably less resistance to breathing, and the results are of importance not only to mine workers but also to firemen and other workers who are liable to encounter poisonous gases in the course of their occupation

Distillation under Low Pressure —The extraction from solutions of solids which readily undergo chemi cal change at high temperatures necessitates usually some form of vacuum still In the *Chemiker Zeitung* of Feb 19 will be found the description of a patent still which embodies some new features In the usual type of still, the resistance to the flow of vapour caused by the pressure of a column of vapour above the liquid often presents difficulty in operating on an extensive scale, moreover, the narrow cross section and rather sharp angle of the outlet tube tend to increase the difficulty These features are to a very great extent eliminated in the new design, in which the vapour is led from a wide tube near the surface of the boiling liquid to the condenser in such a way that very little of the condensed vapour flows back into the liquid The evaporating vessel is made of special resistance glass, which gives better results than porcelain The apparatus is supplied by the firm Greiner and Freid richs of Stutzerbach

The Structure of Silicates.*

By Prof W L BRAGG, F R S

DURING the last few years a number of silicate structures have been analysed by means of X-rays in the Physical Laboratories of the University of Manchester In the course of these investigations, we have found the atomic arrangement in the olivine, chondrodite, phenacite, pyroxene, and amphibole groups amongst the silicates of divalent metals, and in a number of aluminium silicates such as the forms of Al_2SiO_5, staurolite, topaz (analysed also by Pauling), beryl, and the zeolite analcite Other silicates analysed are titanite, and benitoite containing titanium, danburite containing boron, zircon (analysed also by Vegard) and thortveitite A group of workers has carried out these analyses, important contributions being made by Warren (pyroxenes and amphiboles), Zachariasen (titanite, thortveitite, benitoite), Naray (staurolite, cyanite), Taylor (forms of Al_2SiO_5 and analcite), and West (chondrodite group) Warren has just reported an analysis of the melitite group In addition, Menzer has analysed the garnet group, and Jaeger the family of compounds to which ultramarino belongs Preliminary observations have been published by Schiebold on the felspars, and by Mauguin on the composition of the micas So much ground has been covered that it is possible to review the silicates as a class of compounds, though of course such a survey must be of a very preliminary character

In the following description, the silicates will be considered in the light of the new knowledge of their atomic arrangement The conclusions arrived at often reflect well known and widely accepted views of their nature, but the X ray analysis has introduced a greater precision and many novel elements

The distinguishing feature of silicate structures may be described as their intermediate position between salts of acid radicals on one hand, and metallic oxides on the other We may consider the way in which oxygen is associated in crystal structures with the successive elements magnesium, aluminium, silicon, phosphorus, sulphur, and chlorine The last three form acid radicals $(PO_4)^{3-}$, $(SO_4)^{2-}$, $(ClO_4)^{1-}$, and these self contained groups (and also complicated groups such as $(S_2O_7)^{2-}$) combine with metallic ions to form salts Silicon also forms self contained groups such as $(SiO_4)^{4-}$, $(Si_2O_7)^{6-}$, and more complicated forms, which may, if we choose, be considered as acid radicals of the usual type The novel feature is introduced by its additional power of forming *silicon oxygen complexes with indefinite extension in space* It is this feature which gives rise to the vast variety of silicates and explains the difficulty of assigning chemical formulæ to them as if they were ordinary salts

The rôle played by silicon in the inorganic world has been compared to that played by carbon in the organic world, but there is an essential difference between them In organic chemistry the great variety of compounds is due to the possibility of continuing the link between carbon and carbon so as to form more and more complex groups In the silicates, there often is a similar indefinitely extended linking, but it is always one in which an oxygen atom is interposed between two silicon atoms The extended silicon oxygen linking is a transition towards the ionic lattices which metals such as magnesium form with oxygen The passage is the more gradual because aluminium can replace silicon in a silicon-oxygen complex, and at the same time can replace a metal such as magnesium Our very use of the term 'silicate', however, implies a separation of the silicon-oxygen groups in a somewhat arbitrary way from the rest of the structure and a consideration of them as acid radicals, and there is good reason for regarding the silicon oxygen bond as essentially different from the polar bond in an ionic crystal of metal and oxygen

In all compounds hitherto analysed, silicon is found at the centre of a regular tetrahedral group of oxygen atoms The oxygen atoms are about 2 6 A apart, and the oxygen silicon distance is 1 6 A These tetrahedral groups can link together by sharing an oxygen atom In general, the lower the ratio of oxygen to silicon in a silicate, the greater is the extent to which this linking takes place In this way, a range of structures is built up with a successive extension in space of the silicon oxygen linking, represented at one end by the orthosilicates with *independent* groups $(SiO_4)^{4-}$, and at the other end by the forms of silica such as quartz which W H Bragg and Gibbs first showed to be a structure of linked tetrahedra where *every* oxygen atom is shared by two silicon atoms

We can distinguish the following forms of silicon oxygen complex

(*a*) *Orthosilicates* —Independent groups $(SiO_4)^4$

(*b*) *Self contained Groups* —These are formed by linking a finite number of tetrahedral groups Examples are $(Si_2O_7)^{6-}$, $(Si_3O_9)^{6-}$, $(Si_4O_{12})^{8}$, $(Si_6O_{18})^{12-}$ The latter three groups are formed by linking three, four, or six tetrahedral groups in a ring (the sixfold ring in beryl is a striking example)

(*c*) *Silicon Oxygen Chains* —In the pyroxenes there is a simple chain of tetrahedral groups, each sharing an oxygen atom with its neighbours on either side, and thus leading to a composition represented by $(SiO_3)^{2-}$ It is interesting to note that this linking found by Warren and the author was predicted shortly before by Machatschki In the amphiboles two such chains are joined side by side by a further sharing of oxygen atoms or ' condensation ', leading to a composition $(Si_4O_{11})^{6-}$ These chains in the pyroxenes and amphiboles (and probably other types of chain in other compounds) lie side by side They are like acid radicals with indefinite extension in one dimension, and are bound together by the metallic ions They are parallel to the fibre direction in the fibrous forms which these compounds often assume

(*d*) *Silicon Oxygen Sheets* —If three oxygen atoms of each tetrahedral group are shared, the resulting ratio will be represented by $(Si_2O_5)^{2-}$ No compounds of this type have yet been analysed, but it is interesting to note two features The most direct way of linking tetrahedral groups into sheets leads to an arrangement which has hexagonal symmetry, and the dimensions of the network are precisely those of the basal plane of mica (measured by Mauguin) It may be that such sheets will be found to form the basis of the scaly minerals, such as mica, chlorite, and talc, which have a marked basal cleavage and pseudo-hexagonal structure

(*e*) *Three dimensional Silicon Oxygen Networks* —If every oxygen of the tetrahedral groups is shared between two silicon atoms, the structure will be silica, SiO_2 Machatschki first pointed out that if a certain proportion of the silicon were replaced by aluminium, the result would be a silica like arrangement of linked tetrahedra which had a total negative charge, and into which in consequence metallic cations could be incorporated This is the essential feature of ultramarine and the *zeolites*, and according to Schiebold

* Lecture delivered before the Mineralogical Society on Mar 18

of the *felspars* In some zeolites the ratio of aluminium to silicon is quite low, so we have justification for describing these structures as having acid radicals with endless extension in three dimensions The bearing of this on the ease with which the water content is changed and metallic ions substituted in the zeolites without breaking down a crystal, is obvious

These silicon oxygen complexes are bound together by metallic ions, which fit into the spaces between the large oxygen atoms The way in which the cations are incorporated is very interesting I first pointed out the prevalence in silicate structures of close packed regular groups of oxygen atoms, as if many cations such as Be , Al , Mg , Fe , Ti fitted into close packed groups of four oxygen atoms at the corners of a tetrahedron, or six at the corners of an octahedron, with little distortion Larger ions such as K , Ca , Na have often more oxygen atoms round them, and the group is distorted This is natural, for while four or six spheres packed together assume a regular tetrahedral or octahedral form, eight spheres can be packed together more compactly by a less regular arrangement than that at the corners of a cube In the next place, these metallic ions appear to be attracted to the oxygen atoms which have only *one* link to silicon Oxygen atoms linked to two silicon atoms have little external field, as if their valency were saturated It is very likely, as Lowry has insisted, that we must regard the silicon-oxygen link as wholly or partly a homopolar bond Oxygen atoms with a single bond to silicon behave as if they had a single charge $-e$, those with a double bond as if they were uncharged Another very important principle enters, which Pauling was the first to point out, in a general treatment of ionic compounds The metallic atoms are so incorporated into the structure that there is a *local balancing of electric charge* between cations and the negatively charged oxygen atoms These features are beautifully illustrated by models of silicate structures

West and myself, in a paper on the structure of certain silicates in 1927, directed attention to the *importance of oxygen in silicate formulæ* Oxygen atoms cannot be removed from the structure without breaking up the regular groups, and in most cases, owing to their relatively large size, additional oxygen atoms cannot be incorporated in the unit cell This applies not only to the oxygen atoms which are linked to silicon, but also to additional ions O″, OH′, F′ which are part of the structure, the latter ions taking up the same space as oxygen On the other hand, Al can replace Si or Mg, Mg, Fe, and Mn are interchangeable, Ca can replace Na, and so forth, in the familiar way Hence in giving the atomic composition of a silicate after a chemical analysis has been made, the relative numbers of the constituents must be so expressed that the absolute number of oxygen atoms is correct for that particular type of crystal This immensely simplifies the problem of composition in such substances as the silicates where isomorphous replacement is so frequent Mauguin's work on the micas, Warren's on the amphiboles, and Berman's study of the melilite group, afford examples The relatively large size of oxygen, and the constancy with which a distance of about 2 7 A between oxygen centres appears in the silicate structures, make it convenient to think of the silicates as based on an oxygen framework which determines their dimensions, a fact of which considerable use was made in the earliest analyses

Although so little ground has been covered we can begin to see the general lines on which this interesting class of inorganic compounds is based The technique of X ray analysis has reached a stage where the complexity of the structure is no barrier, for examples already worked out are as complex as any we are likely to encounter

A Large Power Plant at Billingham-on-Tees

IN a paper read to the Institution of Electrical Engineers on Mar 13, H A Humphrey, D M Buist, and J W Bansall gave a complete description of the new industrial power plant which has been erected by Imperial Chemical Industries, Ltd , for the factory at Billingham on Tees belonging to Synthetic Ammonia and Nitrates, Ltd The conditions governing the design of this power plant differ from those relating to a public electricity supply station The extension programme required nearly 7000 tons of steam per day for process purposes as well as 37,500 kilowatts of electrical power The quantity of steam required for process purposes is double that required to generate the electrical energy Hence the boiler plant capacity had to be made three times as great as if electrical power only had been required

Chemical works have an almost constant load , in technical language, their load factor is a hundred per cent and continuity of supply is of vital importance A cessation of power would not only cause a loss of output, but would also upset the steady conditions of temperatures and pressures on which the satisfactory operation of the plant depends The power plant, therefore, must have a sufficient stand by plant and means for bringing that plant rapidly into operation Everything has to be considered on the lines of ' safety first ' As the output of the plant has to be as great as that of the largest electricity station in Great Britain, great attention was paid to securing economy, in the generating costs

It was considered that 856° F was the highest safe temperature for ordinary steel superheaters, as a great deal has yet to be learned about ' creep ' stresses at this temperature Considerations of safety, therefore, led the designers to adopt a maximum boiler pressure of 815 lb per square inch As high pressure boilers must have distilled water feed, and as only sixty per cent of the necessary supply could be obtained from the condensed steam, 2500 tons of water have to be distilled every day to add to the ' make up ' feed

By passing the total amount of steam generated, including that required for process purposes, 23,800 kilowatts are obtained Two turbo alternators, each of 12,500 kilowatts, provide the working units, and one is added as a reserve It was stated that the estimated cost of the electric energy generated in the station is well below the cost of any electric generating station in the world depending on coal as fuel This is attributed to the use of the high pressure and high temperature steam The primary turbines pass a greater quantity of steam than would be available in an ordinary power station Owing to the locality, the coal is cheap, and there is an abundant supply of cooling water The load factor also is the highest possible

An ingenious method of supplying the two boiler and pulveriser buildings is adopted The raw coal is brought in by rail and dropped into underground bunkers, from which it is raised by hoists to overhead belt conveyors It is thus carried to overhead steel bunkers in the pulveriser house, where it falls through chutes to the weighers and thence to the mill hoppers,

where it is pulverised It is next carried to an overhead cyclone separator by an air stream driven by exhauster fans From the cyclones the pulverised coal drops through rotary air locks to screw conveyors, which distribute it to the fuel bunkers, of which there is one to each boiler From these bunkers the powder passes through feeders driven by motors, the speed of which can be varied Finally, it is picked up by the air stream from the primary air fans and fed to the burners The air for combustion is supplied by forced draught fans after having been brought to a temperature of about 500° F by preheaters

The main generating units consist of three 12,500 kw high pressure primary units and two 12,500 kw intermediate pressure condensing turbines The turbines run at 2400 revolutions per minute, and are direct coupled to three phase alternators This station marks an important advance in the design of high temperature and high pressure power plants It is the largest high pressure pulverised fuel plant in the world

University and Educational Intelligence.

MANCHESTER —A Consultative Committee on Cancer Research consisting of representatives of the University and of the Manchester Committee on Cancer, including the Christie Hospital and the Radium Institute, has been established The research work will be conducted in the University laboratories and will be directed and controlled by the Consultative Committee Dr C C Twort, who has been working nder uthe direction of the Manchester Committee on Cancer, has been appointed as director of the Department of Cancer Research

OXFORD —The Latin oration delivered on Mar 19 by the outgoing Senior Proctor, Mr L H Dudley Buxton, of Exeter College, contained an appreciative reference to Prof R V Southwell, who comes from Cambridge to succeed Dr Frewen Jenkin as professor of engineering science, and to Prof R Robinson, who takes the place of the late Prof W H Perkin in the Waynflete chair of chemistry A tribute was paid to the skill of the latter in the by paths of music and horticulture Reference was made to the increasing pressure upon library space caused in part by the desire of natural science to "extend beyond the flaming boundary walls of the universe" It was to be hoped that the labours of the Commission, the appointment of which was made possible by the munificence of our cousins in America, would be able to solve the difficult question of library accommodation In view of the invasion of the seat of the Muses by factories, noisy motor traffic, and of the sky itself by aeroplanes and the smoke of furnaces, it was not wonderful that the Radcliffe Observer (Dr Knox Shaw) should have forsaken his post of observation for "thirsty Africa", where the stars are still visible through a cloudless atmosphere Finally, the proposed zoological garden for the delectation of the populace is not regarded by all with approval

THE Royal Society of Medicine, 1 Wimpole Street, W 1, has accepted, as a trust, the sum of £1000 presented by Mr Norman Gamble for the purposes of providing a prize of £50 every fourth year for the best original work in otology carried out by any British subject, lay or medical, during the preceding four years, the balance of the fund to be used for the purpose of awarding grants in aid of research work in otology. Applications for the prize and for grants in aid must be received by the secretary of the Society not later than Sept 30 next

Historic Natural Events

Mar 29-31, 1901 **Snowstorms** —During the passage of a deep barometric depression across Ireland and Scotland, heavy snow fell in North Wales, Scotland, and the north of England, mainly on Mar 29 In some places the depth of snow was three feet on level ground, and it was piled by the wind in great drifts, especially on the Snowdon Range

Mar 30, 1912 **Antarctic Blizzard** —After reaching the south pole on Jan 17, Scott met with calms and light winds with powdery snow which formed a great hindrance to travel Finally, on Mar 20, a blizzard set in, so thick and violent that his party could not leave their tent A gale from west south west and south west continued for at least ten days, and was still blowing when Scott made the last entry in his diary on Mar 30 Every day the party had been ready to start for the depot, only eleven miles away, which would have saved them, but the air was full of whirling drift, and travel was impossible

Mar 30, 1924 **Floods** —The end of March and the beginning of April were marked by heavy rain and extensive floods in Europe, which were accentuated by a sudden thaw following a heavy snowfall In Poland at the end of March the Vistula stood 27 feet above its normal level, a height said not to have been recorded since 1570, and there was much damage and suffering In Jutland a newly built dam burst, and in Spain and Portugal the rivers overflowed their banks, Seville was flooded and many persons were drowned There were extensive landslides in Granada and northern Italy, and in Switzerland traffic was impeded by the heavy falls of snow which blocked the passes

April 1, 1427 **Heavy Rain** —It is recorded in Fabyan's "Chronicles" that "This yere was unreasonable of Wederynge, for it reyened mosli contynually from Ester to Myghelmasse, where through hay and corne was greatly hyndered"

April 1, 1917 **Great Snowstorm** —On the afternoon and evening of April 1, which was Palm Sunday, heavy snow fell in western Ireland, especially in East Clare By 5 30 P M it was nine inches deep on the roads about Broadford, and on the morning of April 2 all the roads were blocked by snow drifts several feet deep More snow fell on April 3, and the roads were not freed until the following day On the night of April 1, there was an intense frost, and two men riding home over a mountain pass were killed by the cold

April 1, 1922 **Landslide** —Heavy rains in Switzerland at the beginning of the month caused a serious landslide near Le Bouveret (Valais), in the Rhone valley The village of Les Evouettes was partially buried Floods were afterwards reported from all parts of the country and also in the Rhone valley in France, at Lyons the lower part of the town was under water There was a considerable amount of minor damage by avalanche and landslide throughout the month, owing to the continued rainfall

April 2-3, 1909 **Heavy Rain** —With depressions in the Atlantic and Mediterranean, heavy rain fell over the greater part of Ireland The average rainfall in the two days over the whole island was 1 69 in., corresponding with a total precipitation of 3558 million tons, or 797,000 million gallons of water The heaviest falls occurred in the south and south west, where several places received more than five inches

April 3, 1901 **Blood-rain Plant** During March and April the large evaporation tank at the former headquarters of the British Rainfall Organization in Camden Square was invaded by a microscopical water plant, which on April 3 was identified by Mr

V H Blackman as *Sphærella pluvialis*, the 'blood-rain plant' The water assumed a deep crimson tint, and resembled a pool of blood This organism is usually found in small pools, the water of which is occasionally carried up into the air by small whirl winds and afterwards falls as 'blood rain'

April 4, 1901 **Phosphorescent Sea**—At 8 30 P M, in the Persian Gulf, the officers of the s s *Kilwa* saw the sea instantly covered with faint moving phosphorescent light, not visible continuously as in ordinary phosphorescent displays, but the sea appeared like a field of corn rippling under a fresh breeze In a few minutes the ripples grew more regular in direction and appearance, coming from south south east, and as each ripple of light reached the ship, phosphorescent 'droppings' appeared close to the ship, the water having the appearance of the starry heavens, or as if large handfuls of small pebbles had been thrown into a lake of phosphorus The ripples were very regular, at half second intervals After a few minutes, the ship passed the centre of the display and the ripples came from north north west Their apparent speed was about 60 miles a minute, they were ripples of light only, there being no movement of the water

April 4, 1905 **Great Indian Earthquake**—The Kangra earthquake originated in the north eastern Himalayas, the meizoseismal area including Kangra and Dharmsala, where more than 18,000 persons were killed The disturbed area is one of the largest known, being little short of two million square miles The depth of the focus was estimated to lie between 12 and 21 miles The earthquake was unusual in one respect There were no dislocations visible on the surface, but a new line of levels carried out through a secondary epicentre at a distance of 120 miles from Kangra showed that the district, including Dehra Dun, had risen about 5 inches

April 5, 1926 **Record Rainfall in California**—At Opid's Camp, on the west front of the San Gabriel range, a rainfall of 1 02 in was registered in one minute The weather station at this place is equipped with a weighing raingauge, which makes an automatic record A second gauge of the same pattern had been installed temporarily alongside the regular gauge, and the two gauges showed the same reading

Societies and Academies

LONDON

Geological Society, Feb 26—S E **Hollingworth** The glaciation of western Edenside and adjoining areas, and the drumlins of Edenside and the Solway basin In the lowland areas the threefold sequence of Early Scottish, Lake District Edenside, and late Scottish glaciations is recognised Almost the whole of the deposits are referable to the maximum of the second or main glaciation A great flood of ice travelled anti-clockwise around the northern end of the Lake District—first northwards towards the Solway, and then westwards and south-westwards into the Irish Sea Basin, it was joined en route by ice from the Lake District valleys Some twenty stages in the retreat from the Eden back to the valley-glacier stage are recognised The ice-fronts were, during the retreat, parallel to the trend of the drumlins over extensive areas This unexpected result led to the study of the drumlins of the much wider area, embracing all Edenside and the Solway Basin, from which it appears that the drumlins were formed at the maximum of the Main or Lake District Edenside glaciation, and not—as has been frequently claimed for other areas—at a late stage

Physical Society, Feb 28—C N H **Lock** The equations of motion of a viscous fluid in tensor notation An outline of the tensor calculus for three dimensions is given, and an attempt is made to develop the theory of the motion of a fluid, by tensor methods, as far as the general equations of viscous flow—W L **Watton** A new type of Dewar flask, for use as a calorimeter The water equivalent of a new type of Dewar flask, of which the inside is of copper, has been measured at laboratory temperatures, and found to be more constant than the usual type—R O **Cherry** Field intensity measurements around some Australian broadcast stations A simple loop, condenser, and valve voltmeter circuit has been employed and careful tests show that this method is available for the measurements of intensities as low as 1 millivolt/metre The field strength contours of three broadcast stations have been determined From these the following conclusions have been drawn (i) Very rapid attenuation of the signal is caused by Australian forest areas, this curtails enormously the areas for which a satisfactory service is provided (ii) The effective conductivity of the various types of ground surface met with varies from 4×10^{-13} to $0\ 07 \times 10^{-13}$ e m u, according to the number of trees in the areas covered (iii) The use of a longer wave length gives a marked increase of intensity at distant points beyond forest areas (iv) For daylight transmission over sea water up to a distance of 85 miles, after the application of curvature corrections to the intensity, Sommerfeld's formula is correct, to within the limits of experimental error (v) The efficiency of radiation of the three aerials examined ranges from 48 per cent to 60 per cent Atmospherics and other disturbances are less prevalent in Victoria than in Europe or America

Institute of Metals (Annual Meeting), Mar 13—D **Hanson**, S L **Archbutt**, and **Grace W Ford** Investigation of the effects of impurities on copper Part 6 The effect of phosphorus on copper Phosphorus removes oxygen from copper and improves its casting properties Small amounts of oxygen can be found together with phosphorus in copper, depending on the amount of phosphorus present Removal of oxygen by phosphorus improves the cold working qualities of copper Copper containing up to 0 95 1 2 per cent phosphorus can be hot rolled, and up to 0 79 0 95 per cent cold rolled from cast billet Phosphorus improves all mechanical properties of copper studied, and raises the softening temperature of cold-worked material It is seriously detrimental to electrical conductivity The wrought alloys of higher phosphorus content exhibit a small amount of age-hardening after suitable heat treatment—R **Genders** The aluminium brasses Over certain ranges of composition, the presence of aluminium in brass has a beneficial influence in several directions, especially as regards resistance to corrosion and to oxidation at high temperatures The composition of the alloys can be adjusted to give a wide range of mechanical properties—C F **Elam** The diffusion of zinc in copper crystals This only takes place to a limited extent at high temperatures When a β brass crystal was heated in zinc vapour, a layer of γ brass was deposited which was also a crystal The relationship between the two crystals was found to be sometimes parallel growth and sometimes a twin—L **Davies** and L **Wright** Protective value of some electro-deposited coatings Specimens of steel, brass, phosphor bronze, and copper were plated with cadmium, zinc, nickel, and chromium, of thicknesses 0 0001 in, 0 0005 in, 0 001 in, and 0 002 in, and exposed to corrosion

sprays of salt and sulphuric acid Cadmium afforded better protection than zinc against the sulphuric acid spray Against the salt spray, the thinnest deposits of zinc gave better protection than the corresponding cadmium deposits In general, for equal thicknesses of zinc and cadmium, the intrinsic protection afforded by the zinc more than compensates for its higher solution potential Chromium deposits afforded no protection whatever to steel, but very good protection was afforded to the non ferrous basis metals A deposit of 0 002 in nickel is necessary to give any degree of permanent protection to steel For general purposes, nickel deposits are most suitable, but no deposit can be recommended unless the service conditions are known —**R Lancaster and J G Berry** A note on zinc base die casting alloys Small quantities of magnesium added to a zinc base alloy, hardened with copper and aluminium, causes a variation in the physical properties, and a distinct change in the crystalline structure —**Bernard P Haigh and Brinley Jones** Atmospheric action in relation to fatigue in lead An oil bath round the test-piece, or even a water bath, greatly delays fatigue in lead, and a thin layer of grease delays fatigue appreciably A bath of acetic acid appears to eliminate fatigue in lead, although a thin film of the same acid does not do so The fatigue fracture of lead is intercrystalline only round the margin It appears that oxygen diffuses through lead subject to cyclic stress, and that, at an appreciable depth below the surface, it provokes a conjoint chemical and mechanical action that leads to fatigue cracking —**W R D Jones** A note on metallic magnesium Redistilled magnesium of 99 99 per cent magnesium is obtainable at such a reasonable price, in view of its purity, that it can be used in metallographic researches

Edinburgh

Royal Society, Mar 3 —**W N McClean** River flows of the Ness Basin After explaining briefly the need for flow measurements and for continuous records of water levels on our river systems, the author points out the peculiar value of the Ness Basin for navigation, fishing, water supply, and water power The measurements described form the basis of the quarterly reports giving the daily rainfall, water level, and flow of the rivers of the Ness Basin (See Nature, Mar 1, p 334)—**Gertrude Lilian Elles and Cecil Edgar Tilley** Metamorphism in relation to structure in the Scottish Highlands The tectonic structure of the Dalradian sediments of the south west and central Highlands is considered in detail in relation to the regional metamorphism which these rocks display A zonal metamorphic map of the greater part of the area has been made The fundamental large scale folding of the type postulated by E B Bailey is confirmed, but a different structural interpretation of the Loch Awe region is suggested The identity of the Ardrishaig and Ben Lawers schists as seen in the critical area in the vicinity of Dalmally is upheld and the rocks of the Loch Awe basin are considered as a continuation of the rock sequence of the Cowal area A table of correlations of the rocks of the several districts (Islay, Ballachulish, Loch Awe, Loch Tay, etc) is given, the stratigraphical sequence as developed beginning with the Eilde Flags Individual correlations include

Islay Lime stone and Black Schists	=Ballachulish Limestone and Slates	=Tayvallich Limestone and Schists	=Blair Atholl Series

and the identity of the well-known boulder beds of Portaskaig, Loch na Cille, and Schiehallion The metamorphism is regarded as developing in an original Dalradian geosyncline a depth metamorphism in which temperature and the stress necessarily incident upon increase of temperature have been the prime factors The development of large scale recumbent folding during this process has led to inversion of the metamorphic zones over wide areas

Paris

Academy of Sciences, Feb 17 —**A Buhl** The planification of families of analytical surfaces —**Marcel Brelot** The equation $\Delta u = c(x, y)u(x, y)(c>0)$ —**Michel Fekete** The changes of sign of a function in a given interval —**Basile Demtchenko** A mixed problem —**Vladimir Bernstein** Integral functions and Dirichlet's series —**Paul Lévy** Some inequalities relating to integral functions —**L Pirot** The determination of the astronomical positions in view of the study of the deviation from the vertical in the peninsula of Brittany —**Luis Rodés** The diurnal and annual periods in the distribution of 1944 earthquakes recorded by the same seismograph The analyses show that changes of temperature due to the sun, though slight, are an important factor in the production of earthquakes —**D Chalonge and Ny Tsi Zé** The continuous spectra of hydrogen connected with the Balmer and Paschen series —**G Déjardin and R Ricard** The structure of the first spark spectrum of mercury (Hg II) —**J Perreu** The limiting heat of solution of sodium hyposulphite and of hydrated magnesium sulphate —**Armel Sévault** The special aluminium bronzes with zinc, silicon, and antimony Tables are given showing the influence of zinc and of silicon on the hardness of aluminium bronzes —**Ch Bedel** Compact fused silicon and the density of this element Accurate density measurements on samples of silicon prepared in various ways showed that crystallised silicon and fused silicon have the same density, 2 33, provided that the fused silicon, which is liable to contain some small cavities, is powdered before taking its density —**Georges Laude** New syntheses of cyanic acid and urea by oxidation of carbon and its derivatives in the presence of ammonia The oxidation of numerous organic compounds was effected by a solution of potassium permanganate in the presence of concentrated ammonia In every case the production of a cyanate was proved this included even sugar carbon —**Deluchat** A class of benzene glycols A description of the preparation and properties of glycols of the type $C_6H_4(CH\ OH\ R)_2$, in which R was methyl, ethyl, propyl or benzyl —**R Cornubert** The possible existence of several dibenzylidene-cyclo pentanones —**Marcel Godchot and Max Mousseron** The hydrogenation of octohydrophenazine —**Ch Brioux and Edg Jouis** The neutralising action of hydraulic lime silicates on the soil —**Cannon** The sympathetic system as an agent of stability of the organism After removal of the two sympathetic trunks, the animals (dog, cat, ape) lived in the laboratory several months The basal metabolism was unchanged and the reproductive functions remained intact Temperature control was affected and resistance to heat and cold was reduced The other changes produced were such that the animals if set free could not long maintain their normal existence —**F Rathery, R Koubilsky and Mlle Yvonne Laurent** The glycæmic recharge of the liver —**Philippe Fabre** The law of neuromuscular stimulation by short electric discharges in man —**A Leulier and L Revol** The localisation of virtual adrenaline —**G Mouriquand, A. Leulier and P Sedallian** The arrest of the diphtheric intoxication by the placenta The experiments described show that in the guinea-pig the placenta arrests the diphtheric toxin, or at least, the phenomena of intoxication to which it gives rise, especially so far as the suprarenal capsules are concerned.

Diary of Societies.

FRIDAY, MARCH 28.

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS (at Middlesex Guildhall Westminster) at 3 —Annual Meeting

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (Clinical Meeting at King's College Hospital), at 5

PHYSICAL SOCIETY (Annual General Meeting) (at Imperial College of Science), at 5 —Presentation of the Duddell Medal to Prof A A Michelson —At 5 45 (in Electrical Engineering Department of the City and Guilds Engineering College) —Exhibition of Research Work now in Progress

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre, jointly with Manchester Association of Engineers) (at Manchester), at 7 15 —J Calderwood Marine Diesel Installations, with particular reference to Auxiliary Machinery

JUNIOR INSTITUTION OF ENGINEERS (at Royal Society of Arts), at 7 30 —G S Taylor Industrial Accidents, their Cause and Prevention (Gustave Canet Memorial Lecture)

ROYAL SOCIETY OF MEDICINE (Epidemiology Section), at 8 —Dr W Fletcher Typhus like Diseases of Unknown Ætiology

PHILOLOGICAL SOCIETY (at University College), at 8 —L C Wharton Slav Philologists Congress

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir Ernest Rutherford The Transmutation of Matter

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub-Centre).

SATURDAY, MARCH 29

BRITISH MYCOLOGICAL SOCIETY (in Botany Department, University College), at 11 A M —Miss E M Blackwell and Miss G M Waterhouse Spores and Spore Germination in the Genus *Phytophthora* —Miss M Brett Stemphylium Alternaria —K St G Cartwright The Study of Basidiomycetes in Culture —S Dickinson The Genetics of the Smut Fungi —Exhibition by S P Wiltshire on The Preservation of Petri Dish Cultures of Fungi

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Sir Ernest Rutherford Atomic Nuclei and their Structure (4).

MONDAY, MARCH 31

INSTITUTE OF ACTUARIES, at 5 —C. F Wood Experiments in Modified Forms of Select Mortality Tables

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —Capt. P P Eckersley and others Discussion on Loud Speakers

ROYAL SOCIETY OF ARTS, at 8 —Comdr F G Cooper Aids to Navigation (Thomas Gray Lectures) (2)

TUESDAY, APRIL 1

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr C Singer The Passage from Mediæval to Modern Science (4) The Scientific Crux

ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —Major R W G Hingston In the Tree Roof of the Guiana Forest.—Prof A Meek Further Notes on *Bipinnaria asterigera* from the Northumberland Plankton (Echinoderma).—Nellie F Paterson The Bionomics and Morphology of the Early Stages of *Paraphædon tumidulus* Germ. (Coleoptera, Phytophaga, Chrysomelidæ).—C. P Gnanamuthu The Anatomy and Mechanism of the Tongue of *Chamæleon carcaratus* (Merrem).—J Omer Cooper Report on the Gyrinidæ (Coleoptera) collected during Dr Hugh Scott's and Mr Omer-Cooper's Expedition to Abyssinia.

LONDON NATURAL HISTORY SOCIETY (at Winchester House, E C), at 6 30.—A. D Middleton Red and Grey Squirrels

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers' Club, Manchester), at 7 —H A Humphrey, D M Buist, and J W Bansall The Imperial Chemical Industries Limited's Steam and Electric Power Plant at Billingham.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7 —H Pickwell The Pilgrim's Way

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7 30 —Capt. J S Irving Some Problems Encountered and Overcome in the Design and Construction of the *Golden Arrow* —J H Hyde and Dr F Aughtie Measurements made of the Power and Efficiency of a Motor Lorry Gear Box

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (Annual General Meeting) (at Leicester Museum), at 8

WEDNESDAY, APRIL 2

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—R. H Barfield Recent Developments in Direction Finding Apparatus. (Part 1 Medium Wave Apparatus, 250-600 metres. Part 2. Short Wave Apparatus, 12 50 metres)

INSTITUTION OF ELECTRICAL ENGINEERS (Tees Side Sub-Centre) (Annual General Meeting) (at Cleveland Technical Institute, Middlesbrough), at 7 —At 7 30 —L C Grant The Breaking Performance of High Power Switchgear and of a New Form of Quenched Arc Switch

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—Prof M Eldin Bey The Detection and Identification of Alkaloids in the Saliva and Salivary Glands.—Ella M Collin The Separation of Cadmium and Copper in Spelter and Zinc Ores by Internal Electrolysis —A F Lerrigo The Routine Detection of Nitrites in Milk.—Dr J C Ghosh A Method for the Determination of Titanium as Phosphate

ROYAL SOCIETY OF ARTS at 8

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section) (Reception at Wellcome Historical Medical Museum) at 8 30 —Lord Dawson of Penn Henry Hill Hickman

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 8 30 —C M Page, P J Verrall Dr R D Langdale Kelham and Capt A. R Maxwell Discussion on Amputations and their Relation to the Artificial Limb

ROYAL MICROSCOPICAL SOCIETY (Biological Section).

THURSDAY, APRIL 3

INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting) (at St Ermins Westminster), at 3 —Dr J T Dunn and Dr B Moore Pulverised Fuel

LINNEAN SOCIETY, at 5 —H Lister Some Observations on the Comparative Morphology of the Protozoan Fauna, etc —Prof H S Holden Some Wound Reactions in *Ankyropteris corrugata* —Dr J M Cowan Botanical Exploration through North west Persia

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Prof J B. S Haldane Some Problems of Genetics

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts) at 6 30 —P Grimault Operation of the Aero-Postale Service in Europe

CHEMICAL SOCIETY, at 8 —Prof C S Gibson, A. R. Penfold, and J L. Simonsen The Essential Oil of *Backhousia Angustifolia* Part II The Isolation of Naturally Occurring β diketones Angustione and Dehydro angustione —Miss F M Hamer Attempts to Prepare Cyanine Dyes from Quaternary Salts of 2 methylacenaphthpyridine and of methylacridine —Prof C S Gibson E S Hiscocks, J D A Johnson, and J L. Jones 10 Chloro 5 10 Dihydrophenarsazine and its Derivatives Part XII Absorption Spectra —R W Aldis and Prof J C Philip The Production of Fog in the Neutralisation of Alkali with Hydrogen Halides Part II The Significance of the Presence of Ammonia.

OPHTHALMOLOGICAL SOCIETY —Sir Arthur Keith The Genius of William Bowman (Bowman Lecture).

FRIDAY, APRIL 4

INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting) (at Hotel Victoria Northumberland Avenue), at 11 30 A M —Presentation of Medals The Moulton Medal, The Junior Moulton Medal, The Osborne Reynolds Medal —At 12 15 —J A Reavell The Rôle of Science in Industry (Presidential Address) —At 2 15 —H Tongue The High Pressure Equipment of the Chemical Research Laboratory, Teddington

ROYAL SOCIETY OF ARTS (Indian Section), at 4 30 —Lieut -Col Sir Wolseley Haig The Maratha Nation (Sir George Birdwood Memorial Lecture)

FEDERAL COUNCIL FOR CHEMISTRY (at Burlington House), at 4 30

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle upon Tyne), at 6 —A. Read Ship's Electrical Deck Auxiliaries

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (Annual Meeting) (at Chamber of Commerce, Birmingham), at 6 30 —At 7 —A. R Warnes Some Little Known Causes of Stone Decay

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual General Meeting) (at Engineers Club, Manchester), at 7 —Major A. G Church The Attitude of the Government towards Scientific Research

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —Dr E H Rayner W G Standring, R. Davis, and G W Bowdler Studies in Low Power Factor Measurements at High Voltages

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —A L Stanton and others Discussion on Smoke.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7 —Informal Meeting

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —W M Hurrell Visits to Iceland and other Places

GEOLOGISTS' ASSOCIATION (at University College), at 7 30 —A. L. Leach Geological Structure and British Coastal Scenery (Lecture).—A L Leach and A C Young On a Section in River Ravensbourne Valley Gravels at Lewisham.—A. L Leach Recent Excavations in the Shooters Hill Gravel.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University).—A. H. Amery Methods of Extracting Oil from Seed

SATURDAY, APRIL 5

GILBERT WHITE FELLOWSHIP (Annual General Meeting) (at 6 Queen Square, W C 1), at 2 30 —At 3 —Sir Richard Gregory Primitive Astronomy (Lecture).

MINING INSTITUTE OF SCOTLAND (at Glasgow).—Annual Meeting.

PUBLIC LECTURE.

SATURDAY, MARCH 29

HORNIMAN MUSEUM (Forest Hill), at 3.30.—J E. Dallas June Flowers in Alpine France.

SATURDAY, APRIL 5, 1930.

The Rationalisation of Chemists

THOUGHTFUL men and women, surveying the part that science has played in the lives of the present generation, have no illusions concerning its potency, for good or for ill, in controlling the destiny of their successors To have seen science in the grip of Mars, to have watched the wonderful service of chemistry to medicine, is to know how true it is that knowledge applied is power acquired, those who have lived through a clash of arms in which science, whether acknowledged or not, dominated policy, strategy, and tactics, find no difficulty in applying, indeed they are constrained to apply, that same experience to the problems of the post War world In the industrial troubles of to-day—depression, loss of overseas markets, unemployment—they recognise inevitable casualties in the battle of industrial wits, and they know that the struggle must end in favour of the best equipped battalions, if they did not know it before, they realise now the truly vital position of the scientific basis of industry in the nation's life Once again science will dominate policy, strategy, and tactics, and in the intense industrial competition, over the threshold of which we have yet scarcely stepped, tradition will count for little beside knowledge, and pride for nothing compared with progress

What will in the future be the foundation of our national wealth and influence? Not conquest, nor colonisation, our position will depend on the use to which we put our heritage of natural resources Of the basic industries of Great Britain, three—mining, metallurgical, and chemical—are of prime importance These stand sentinel over our future prosperity, it is to these industries, aided at almost every step by engineering, and drawing frequently, as occasion requires, on the resources of knowledge gathered by almost every other science, that we turn for means to exploit our potential wealth The nation which fails to organise its industrial power will scarcely expect to reap commercial rewards, and the nation which fails to employ methods at least as efficient as those of its competitors will have to go out of business

Chemists and chemical engineers have long been considering the position On the commercial side we have seen important amalgamations effected in order to promote efficiency and economy of effort On the scientific side much advance but little reorganisation has yet taken place, although the need grows with the expansion of chemical knowledge and influence Nevertheless, British chemists fully

realise the responsibility of the position occupied by their profession, and whilst they subscribe wholeheartedly to a policy of international fraternity among scientific workers, they are neither unaware nor careless of their own country's needs They are anxious, therefore, to modernise professional machinery in the chemical group of sciences for more effective industrial defence and more rapid progress They desire to put their house in order by eliminating duplicate provision and effort, and thereby consolidating the personnel of the nation's chemical service

Now chemistry, as is well known, instead of remaining a homogeneous unit in the scientific corpus, has almost acquired the status of a sub-group of sciences Since the foundation of the Chemical Society, the first organisation in the world to be established for the special purpose of promoting chemical knowledge, there have grown up various societies of chemists and chemical engineers who concentrate their attention on different branches of the science—how different, chemists alone know! Each plays a worthy part in promoting discovery and application, and any scheme of co-ordination will necessarily have in view the intensification, and not the delimitation, of studies in every field In order that the ground may be more thoroughly surveyed, and to conserve the limited resources of a profession which, on the whole, is in receipt of only a modest competence, Prof J F Thorpe, in his recent presidential address to the Chemical Society, has outlined definite and considered proposals which merit the most careful consideration by the interests concerned A firm believer in co-operation in science and industry, Prof Thorpe seeks to put into practice his principles What appears an impossibly heavy task for the chemical group unaided may become possible by association with other branches of science Hence he proposes to solve the housing problem by co-operation with societies in the mining and metallurgical branches, and to promote co ordination of effort in the chemical branch by fusion of publications and, eventually, of membership

This twofold scheme seems to us to provide at least a firm basis for action. The proposals, by seeking to establish a kind of chemical 'general headquarters' forming a unit in an even more comprehensive scientific and industrial assembly, are thereby invested with an importance which is not only national, but also imperial Many of the principal societies for encouraging the acquisition, marshalling, and dissemination of scientific knowledge, not least those concerned with pure and applied chemistry, are at present restricted in their usefulness by being inconveniently and inadequately housed, libraries are scattered, there is no general information bureau, even meeting rooms have to be borrowed and lent, there is little social intercourse between members of the same branch and less between members of different branches, office organisations are not in close touch—in short, there is lamentable lack, as regards accommodation, of the elementary needs of inter-group efficiency Efforts to remedy the situation have been discussed for the past ten years, but proposals have hitherto been rendered nugatory by the financial burden proving too oppressive for societies supported in so large a measure by the annual subscriptions of their members Even under present conditions the Chemical Society, for example, by the exercise of rigorous economy, finds it only just possible to show a small credit balance when provision has been made for the cost of the publications, which is the chief expenditure

Accommodation and co-operation, then, are the needs to be supplied The joint housing project involves only half the capital expenditure previously envisaged, and it has the merit of securing real co-operation with the minimum disturbance of the constitutions and functions of the participating societies, whilst it will facilitate fusion should this course commend itself at some future time A scheme originating with the mining and metallurgical societies and institutions provided the nucleus of the wider project, which now proposes to secure collaboration by the Empire Council of Mining and Metallurgical Institutions, the Institution of Mining and Metallurgy, the Institution of Mining Engineers, the Iron and Steel Institute, the Institution of Petroleum Technologists, the Institute of Metals, the Institute of Fuel, the Chemical Society, the Society of Chemical Industry, the Institution of Chemical Engineers, and the Institute of the Rubber Industry in seeking financial assistance for the erection of a suitable building to serve as a joint headquarters in Westminster Two-fifths of the space, a veritable 'Chemistry House', would be allotted to the chemical group, and their share of the capital sum involved would be £140,000 In so far as the accommodation then available would not be required for immediate occupation by the participating societies, it would be used by 'tenant' societies directly connected with the industries represented by the constituent bodies The Chemical Society's library would form the nucleus of the new library whilst continuing to function, as at present, as a sectional library. The central library is, of

course, one of the pivots of the whole scheme, as also is the proposed bureau of information

Prof Thorpe fully realises that the problem of raising the necessary money is difficult, particularly in view of the present great depression in industry and the incidence of high taxation He naturally and properly looks, however, to the chief ultimate beneficiaries, namely, the industries concerned, to afford the greater part of the required support As chairman of the appeal committee, he finds among those engaged in industry an eagerness to play a worthy part , of the total sum of £350,000 required, definite promises amounting to £130,000 have been received This is an encouragingly large sum, but encouragement is tempered with anxiety in respect of the remaining £220,000 The Government has, we understand, expressed sympathy with the object in view, but has refused—we hope not finally—to accord any financial assistance

Such is the outline of the important proposals which affect more than twenty thousand of our colleagues Before we turn to the second group of proposals, we would offer one or two observations on this solution of the ' housing problem ' In the first place, we consider the scheme to be conceived in the interests both of science and of the nation, so that we unhesitatingly and whole heartedly support it in principle Whilst we are not willing at this stage to comment on matters of organisation or of detail, matters which will assuredly exercise the leaders of the professions concerned for some time to come, we think the proposals are likely to be effective in their purpose without causing unnecessary disturbance of existing institutions , they have the merit of envisaging more than they are intended immediately to accomplish, and they promise to serve the community Scientific workers obviously cannot themselves bear the whole financial burden incidental to their public service, and we rejoice that industry is found willing to share it with them We invite industrialists to sow with a liberal hand that seed of which they will in due time enjoy the fruit , times are hard, but this is an additional reason for helping to consolidate the ranks of their willing, indeed eager, servants

The attitude adopted by H M Government is, we hope, one which will prove amenable to modification on reflection Some consideration is obviously due, and will presumably be accorded, to the Chemical Society in respect of the surrender of its free tenancy of rooms at Burlington House. In any event, it could scarcely represent the extent of the public interest in the scheme Public money should be expended for the ultimate good of the public as a whole, and in our opinion the scheme which Prof Thorpe has outlined is one which both deserves and demands substantial support from the public treasury We should not like to think that, in its attitude towards the organisation of science for the service of industry, any government of the present day believes that its responsibility can be discharged by merely recording its approval

While rightly insisting on the service which science renders to the growth of industry, Prof Thorpe does not, of course, forget that which industry renders to the advancement of so called 'pure' science He quoted in illustration the certainty of advance in organic chemistry which is associated with the existence in any country of a successful and well-established dyestuffs industry Large research organisations created by firms employing many of the most capable chemists in Great Britain promote progress in directions which are not confined to the special needs of the industry itself, but equally serve other related interests

The further proposals which Prof Thorpe puts forward are concerned with the publications of the Chemical Society and the Society of Chemical Industry and with a plan for joint membership It is suggested that joint publication of four journals, in addition to the annual reports, should be undertaken chemical transactions (monthly), abstracts (A and B together), a publication similar to the American *Industrial and Engineering Chemistry* (monthly), and *Chemistry and Industry*—the news edition (weekly) There are obvious advantages to be secured from such unification, and the proposal merits careful exploration Six years' successful work by the Bureau of Chemical Abstracts, itself a joint board, has shown that co operation in publication is both possible and advantageous, and there are many who look forward to the possibility of extension of the principle Moreover, it is believed that it could be made financially possible for each section of the Society gradually to secure a membership common to both, while preserving financial and administrative autonomy

Granted that ultimate fusion of the two societies is desirable, Prof Thorpe's suggestions reflect practical statesmanship and something more than a superficial knowledge of human nature Whether or not they prove acceptable to chemists without modification, he has performed a substantial service in so carefully exploring the position and in providing a promising basis for discussion The opportunity for action appears to have arrived , chemists will be well advised not to allow it to pass Many years may elapse before it recurs

The Gramophone

Modern Gramophones and Electrical Reproducers By P Wilson and G W Webb Pp xvi + 272 + 12 plates (London, Toronto, Melbourne and Sydney Cassell and Co, Ltd, 1929) 10s 6d net

THE recent development of the gramophone has presented a striking example of the great benefits to be derived when industrial research can be directed upon the basic *phenomena* of an industry Sufficient co-operation between manufacturers cannot always be secured to finance such comprehensive research, and then little more can be undertaken than an initial quantitative definition of industrial *processes*, as distinct from the natural phenomena underlying them, and a subsequent study of empirical changes made in these quantities For a period of some twenty five years, gramophone research was purely empirical and the meagre results gave only a product which the establishment of broadcasting threatened to exterminate Then the whole gramophone industry was suddenly revitalised by the introduction of electrical recording and the matched impedance type of reproducer The present volume deals more especially with these remarkable advances, all of which originated in the Bell Telephone Laboratories in New York and, we would emphasise, were merely by products of an enormous fundamental research

To know their origin, which happened to lie in practical telephone designing, lends a deeper significance to the book Some fifteen years ago, an advanced stage had been reached in the art of accurately analysing fluctuating electrical currents into their component frequencies and in the correlated art of describing and measuring the characteristics of mechanically vibrating systems A part of telephone design was, however, empirical, because speech and hearing could not then be defined quantitatively in physical terms At this stage the step was taken which ten years later yielded results of such importance to the gramophone It was decided to attempt a quantitative definition of speech and hearing Now, although the ear is so delicate, it is so accommodating that its use as a measuring instrument is quite invalid and apparatus of remarkable precision had to be developed Since this apparatus proved to be costly and often complicated and difficult to adjust, it appeared to be of interest only in the research laboratory Nevertheless, one of the instruments, an electrical transmitter developed in the early stages of the research, is now used to produce the modern gramophone record

At the beginning of the book, there is an excellent discussion of the requirements for perfect reproduction A statement by a music critic is worth quoting "When I sit in an acoustically perfect hall (full of people), in the best seat for hearing, and listen to an orchestra, I hear such and such sounds I want to hear precisely this effect from a record" From this simple statement, the dependence of the problems of gramophone reproduction not only upon acoustical, but also upon psychological and physiological considerations, is clearly evident The acoustical and other physical problems occupy the greater part of the volume, although some of the vagaries of the human ear are described

The functions of all the separate parts of the gramophone, consisting of needle, stylus-bar, diaphragm, sound box, tone arm, and horn, are now well understood, and it is interesting to note that of all the readily conceivable forms which a sound-box might have taken, the one which was developed happens to correspond closely with that which modern theory shows to be desirable This theory of the design of the whole system from the needle-point to the mouth of the horn has been developed on the lines of the new electro mechanical acoustics, which utilises the analogies between electrical circuits and mechanical systems Practice lags behind theory because of the difficulties of providing and measuring the constants of some of the required mechanical analogues For example, a condenser can be made having large capacity with negligibly small inductance, but it is difficult to make the corresponding spring having compliance without inertia

From the interesting results given in the discussion of the horn, it is clear that for satisfactory reproduction of low notes the horn must be long and must end in a wide opening For example, the horn used in the 'Movietone' reproducer is 14 ft long, and has a mouth of about 5 ft diameter in order to get a sensibly uniform frequency response over the range from 60 to 7000 vibrations per second The alternative to the use of these long horns lies in electrical reproduction from the record with the aid of a moving-coil loud-speaker, and some seventy pages are devoted to the complicated problems of the pick-up and amplification So far as the realisation of theoretical requirements is concerned, the complete electrical gramophone appears to be less advanced than its acoustical rival There is no discussion of the problems of a sound film gramophone

The inclusion of a work on architectural acoustics in the bibliography of books, papers, and patent specifications, shows that the authors realise the importance of this subject, but no space is devoted in the text to its application in gramophone acoustics There is but little detail of the original wax record, and it would be of interest to know if data upon the physical properties of this wax and of the ordinary record material are available These are, however, comparatively minor points of omission

It is pleasant to find that this, the first serious book on the gramophone, is so well written and trustworthy that it has all the desirable properties of a standard work Since the book was written, still another ingenious application of electro mechanical analogies has resulted in the construction of a motor capable of rotating the original wax master record with remarkable constancy of speed, ensuring that the grooves in the record are even more faithful to the original sound (Elmer, *Bell Labs Record*, 7, 445 50, 1929)

W H George

Science and Philosophy

Philosophy by Way of the Sciences an Introductory Textbook By Prof Ray H Dotterer Pp xv + 469 (New York The Macmillan Co, 1929) 10s 6d net

THIS book well represents the remarkable change which has come over the study of philosophy within living memory People who studied philosophy at one of our universities thirty or forty years ago were almost invariably introduced to the subject on historical lines It was assumed that the best mode of approach to the problems of philosophy lay through the historical systems, beginning with the Greeks and ending perhaps with Kant and Hegel So far as Britain was concerned, it was a study most assiduously cultivated north of the Tweed, and when an English chair of philosophy became vacant, the list of applicants was bestrewn with the syllable 'Mac' Philosophy was regarded as a thing apart, an intellectual luxury, something of a holy mystery The philosopher's colleagues, especially those of the faculties of pure and applied science, were apt to regard his ministrations as harmless diversions, or as interesting attempts to solve problems which, unlike those of physics and biology, were in the nature of the case insoluble. It was all part and parcel of the general attitude of men of science, at a time when positive science was making astonishing progress, and seemed capable of leaving no problem ultimately unresolved

Gradually, however, a change has come over the scene, a change to which both sides have contributed Although, of course, the history of philosophical systems holds an important place in a certain type of university curriculum, yet it has become customary to introduce the student to the main philosophical problems as they appear to the modern mind, to show him what philosophy 'is all about', before plunging him into the history of the systems, and the advanced student becomes aware that the old puzzles have to be viewed in new lights, and that new puzzles have to be added to the old, under the impulse of the strenuous thought that is being devoted to philosophical issues in our time It would be easy to name a whole crop of books, produced since the beginning of the twentieth century, which exemplify these changes in the pursuit and the teaching of philosophy

Not less striking is the changed attitude of men of science, their modified faith in mechanistic explanations of life, and especially of the life of man, their consciousness that every line of scientific inquiry leads to problems which (using the word physics in its older and more general sense) are beyond physics, that is, are metaphysical Hence the present position, that some of our leading men of science are also among our leading philosophers

Dr Dotterer is, of course, not the first teacher to have led his students to approach "philosophy by way of the sciences" But we do not recall any introductory text-book which conducts its reader along this road so thoroughly and competently as the book under consideration Other writers are content to propound the problems of metaphysics, and incidentally to show that they begin where scientific explanation leaves off Dr Dotterer takes the bold course of devoting one half of his book to a survey of the sciences—what they have achieved, and where their difficulties begin A statement of the achievements of astronomy and geology is followed by a statement of the corresponding perplexities Is the world-process teleological? Is reality finite or infinite? What is the relation of time and space? And so on The achievements of physics, chemistry, and mathematics suggest perplexities about the constancy of our units, and the absoluteness or relativity of motion Similarly, the achievements of biology and psychology suggest perplexities about development, and the interrelations of mind and body. Not all his fellow

teachers would agree with the author's attempt to summarise the achievements of science, and some of them might charge him with an assumption of omniscience He took the risk, and all we can say is that we think he justifies himself

So the first half of Dr Dotterer's book leaves us with a somewhat bewildering bunch of 'perplexities', each of which presents a problem in philosophy Some of them are philosophical 'chestnuts', such as the issue between realism and nominalism Among the other problems are the criterion of truth, the problem of being, determinism and its opposite, the authority of values, and the belief in progress

Dr Dotterer has written primarily for students of philosophy, but he has aimed at producing something more than a text book, and in our judgment he has succeeded To make philosophical discussions clear to the general reader is not an easy task, but it is here accomplished The author writes lucidly and forcibly, and his criticism is always marked by modesty and sanity The general reader—and for the present purpose the student of science may be so described—will find this book a most useful introduction to the abstruse but ever alluring problems of metaphysical speculation

Bacteriology in Medicine

The Principles of Bacteriology and Immunology By Prof W W C Topley and Dr G S Wilson In 2 volumes Vol 1 Pp xvi + 587 + xvi Vol 2 Pp viii + 589 1300 + xx (London Edward Arnold and Co, 1929) 50s net

THE authors of this book say, "We have attempted on the basis of our personal experience in post graduate and undergraduate teaching to provide a text book which will be of service to those students of medicine and biology who wish to make a serious study of bacteriology, and its application to the problems of infection and resistance" This very desirable end has led them, we think wisely, to divide the book into two volumes, so as to treat in the first place the biological aspects of bacteria, and after that has been dealt with to pass to the subject of infection and the application of bacteriology to medicine and hygiene

Vol 1 is divided into two parts, the first of these deals with general bacteriology, and after giving a short, but interesting, historical outline, the authors proceed to the biological and physiological characteristics of bacteria—their growth and resistance to physical and chemical agents, serum reactions, bacterial variation, classification, and, finally, they give some practical details and a well-written chapter on the Twort d'Herelle phenomena

Though all these chapters bear evidence of wide reading and good critical judgment, we would specially praise the one on serum reactions and antigenic structure of bacteria This somewhat difficult and, at present, rather confused subject has been made clear to any intelligent reader, and the views of the various writers on this subject are given with great fairness The chapter on bacterial variation is also a very valuable one, and disinfection is treated very fully

The authors have thought it necessary to adopt the American classification This we feel is still crude and unsatisfactory, and we regret its adoption, though possibly if we had been the authors we would have been forced to do as they have done

Part 2 of the first volume concerns itself with the description of the various bacterial species This is well written, and the illustrations are, on the whole, very satisfactory We welcome the absence of detailed descriptions of technique which load up uselessly so many text books on bacteriology Why writers on bacteriology should give half a dozen or more different methods for staining a special bacterium has always been beyond our conception, and it is a joy to find a book where this is not done, and where the authors have deliberately omitted these

Vol 2 deals with bacteriology in its application to medicine and hygiene Part 1 deals with infection and resistance, and in a work of this kind for which Prof Topley has done so much one naturally expects a great deal We have not been disappointed The facts are very clearly put, and the critical work is of a high order Part 2 is very well done, and medical men dealing with any of the bacterial diseases will find valuable information on almost every page

We congratulate the authors on the production of an extremely valuable text-book, one which should find a place not only in every bacteriological and pathological laboratory but also on the bookshelf of every medical man The task must have been a very difficult one, for one must recognise that bacteriological literature is, at present, somewhat chaotic The authors must have read widely, but the strongest feature is the independence shown in departing from the usual text-book routine

Index Londinensis to Illustrations of Flowering Plants, Ferns and Fern Allies Being an emended and enlarged edition continued up to the end of the year 1920 of Pritzel's Alphabetical Register of Representations of Flowering Plants and Ferns, compiled from Botanical and Horticultural Publications of the XVIIIth and XIXth Centuries Prepared under the Auspices of the Royal Horticultural Society of London at the Royal Botanic Gardens, Kew, by O Stapf Vol 2 Pp iv + 548 (Oxford Clarendon Press, London Oxford University Press, 1930) 105*s* net

In October 1929 the first volume of this important work made its appearance It included all plants from *Aa* to *Campanopsis* The editor, Dr Stapf, and his collaborators have now brought their great task one stage further with the issue of Vol 2, which appeared about Christmas 1929, but is dated 1930 It consists of 548 pages and is, therefore, of almost exactly the same size as Vol 1 It comprises references to illustrations of all plants from *Campanula* to *Dysphania* inclusive The Clarendon Press is once more to be congratulated on the excellence of the printing

The work is recognised by very many as one of great utility and a trustworthy and voluminous guide to all who desire to see pictures of plants or parts of plants belonging to the groups cited in the title It should, in this respect, supply every need of the practical gardener, be he florist or arboriculturist, and of the botanist, whether he be systematist, morphologist, or dilettante collector The work will help to direct attention to a good deal of the older literature which has been neglected in the past and frequently contains much that is valuable It will be found to fill many a gap caused by the omission of pictures of intrinsic merit in themselves, but which, for one reason or another, have been entirely left on one side by botanical workers It should also point the way to a proper discrimination in the choice of illustrations in the future

Another important function of the "Index" consists in the revision of the nomenclature of well known large genera such as *Bignonia*, *Croton*, *Pinus*, etc, which hitherto have included a confused medley of plants which, according to modern ideas, should be placed in quite distinct genera

This revision, let us hope, may have some effect in inducing gardeners to name their plants more correctly W C W

Handbuch der biologischen Arbeitsmethoden Herausgegeben von Prof Dr Emil Abderhalden Lieferung 307 Abt 9 *Methoden der Erforschung der Leistungen des tierischen Organismus*, Teil 6, Heft 1 *Methoden der Meeresfischereibiologie Die Methodik fischereibiologischer Untersuchungen an Meeresfischen* Von Adolf Büchmann Pp 194 (Berlin und Wien Urban und Schwarzenberg, 1929) 11 gold marks

To those who may wish to acquire a working knowledge of the methods employed in modern scientific investigations of the sea fisheries, this section of Abderhalden's great 'handbook' can be recommended When considering the subject, it should be remembered that the fisheries biologist is largely dependent upon data derived from relatively small samples for his knowledge of the fish population he studies It should therefore occasion no surprise that great use is made of statistical methods to determine the limitations of the samples taken, and hence to estimate the probability that the samples truly represent the population or stock from which they are taken Indeed, much of the most valuable work accomplished in recent years has been the development of trustworthy technique based on random sampling It cannot be too strongly emphasised that in this field of biological investigation, where results are to be applied to the great problems created by the commercial fisheries, nothing less than critical mathematical analysis can suffice This being so, it follows that the would be research worker will do well to include in his preparation the essentials of statistical treatment of raw data Dr Buchmann's treatise should prove most helpful in indicating the nature of the difficulties lying ahead

The Great Mathematicians By Prof H W Turnbull (The Great Scientists Series) Pp viii + 128 (London Methuen and Co, Ltd, 1929) 2*s* 6*d*

This little volume—one of a series devoted to the history of science—gives, in a very readable manner, an interesting narrative of some of the greatest representative mathematicians from the early Egyptians to Ramanujan In the preface, the author says "Fully conscious of the difficulties of the undertaking, I have written this little book in the hope that it will reveal something of the spirit of mathematics without unduly burdening the reader with its intricate symbolism" Herein lies the key to the whole story, for not only has the subject matter been very judiciously selected, but also the way in which it has been woven into a very human narrative is indeed an outstanding feature

Undoubtedly, in his brief delineation of those great personalities who found in mathematics both an inspiration and a delight, Prof Turnbull has very successfully achieved his purpose, and in so doing has rendered a real service to the popular development of so abstract a subject As the historical account is naturally incomplete, owing to the small size of the volume, a list of books for further reading is given

A Textbook of Light By Dr R Wallace Stewart and Prof John Satterly (The Tutorial Physics, Vol 3) Sixth edition Pp vii + 363 (London University Tutorial Press, Ltd, 1929) 6*s* 6*d*

This popular text-book, designed to carry the student to university intermediate stage, has now reached its sixth edition, in which the type has been re-set and certain sections have been re-written and simplified The opportunity has also been taken to add new matter to the chapter on dispersion, which serves both to offer a pleasant approach to the study of spectroscopy and to provide clear explanations of many common phenomena, such as lunar haloes, which are not always treated well in text-books

Letters to the Editor.

Quantitative Analysis by X-Rays

WE have read with much interest Prof Hevesy's address to the British Association on "Quantitative Chemical Analysis by X rays and its Applications" (NATURE, **124**, 841, 1929) While we are in agreement with many of the statements of that address, our experiments lead us to somewhat different conclusions as to the possibilities and limitations of analysis by X-rays

Qualitative Analyses —The simplicity of the X ray spectrum of an element (particularly of its *K* series), the existence of Moseley's law, the known facts relating to the relative intensities of spectral lines and to the potential required to excite a group of lines, make the X ray spectrum of any substance a comparatively simple one, and give to the identification of the lines a high degree of certainty It is true, however, that the experimental difficulties of producing such a spectrum and of measuring the wave length and intensity of the lines are not inconsiderable

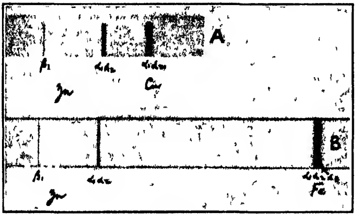

FIG 1

Prof Hevesy discusses the important question of the excitation of the X ray spectrum of the material being analysed This is all important to the practical convenience, to the sensitiveness, and to the quantitative accuracy of X ray analysis Three methods of excitation can be used In the first the material is bombarded in the vacuum of the X ray tube by cathode rays, in the second by Lenard rays outside the vacuum, and in the third, used by Prof Hevesy, by primary X rays which fall on the material either inside or outside the X ray tube

The first method involves all the difficulties of high vacuum technique, and is unsuitable for volatile substances A discussion of these methods cannot be given here, beyond noting that the second method has the important advantage of producing a characteristic spectrum free from general radiation It may be noted, too, that the metals and their alloys lend themselves to the first method, and when water cooled can be subjected to intense cathode ray bombardment The production of a strong beam of X-rays from a non-metal is, however, much more difficult

Prof. Hevesy refers to the sensitivities of analysis by X rays, and to the relative advantages of the optical and X ray methods of spectroscopic analysis, but it is not clear whether his remarks refer to quantitative or qualitative analysis In the detection of a small quantity of a given element in a mixture of elements by X-ray spectroscopy, a much higher degree of sensitiveness can be obtained than Prof Hevesy and other writers on this question have claimed

Fig 1, A, reproduced from a paper by the writers and Mr A H Turner (*Proc Roy Soc*, **124**, 258, 1929), shows the *K* spectrum of a zinc containing 7 parts in 10^6 of copper, and B shows the *K* lines of a zinc containing 3 in 10^6 of iron It is evident that 1 in 10^6, possibly 1 in 10^7, of iron in zinc could have been detected The detection of small amounts of impurities in non metals (usually examined in the form of powders) is more difficult than in metals, as faint lines may be masked by a dark background of continuous radiation from the metal upon which the powder is placed, and by scattered radiation It is, therefore, desirable to use as this metal one of low atomic number (for example, aluminium), and to select a voltage such that the wave length of maximum energy in the continuous spectrum does not coincide with that of the spectral line sought The photographic film must be protected from scattered radiation by suitable screens

Several quantitative methods of analysis by optical spectroscopy are in use One due to Lockyer depends on the variation in the length of certain lines in the arc and spark spectra of an element with the amount of the element present, another, due to Hartley, relies on the persistence of certain lines in the spark spectra of solutions when the element giving the line is present only in very small amount, while the third, and most successful, is based on the discovery of de Gramont that each element has several sensitive lines, or 'raies ultimes', which reveal its presence, in some cases, for so little of it as 1 part in 100,000 The amount of the element present can be determined with fair accuracy by the number of its lines which can be observed Unfortunately, however, for many elements all the lines vanish for concentrations of less than 1 in 10,000, and a further difficulty with a mixture of elements is the masking of the sensitive lines of one element by the strong lines of another

With the X ray method, the entire spectrum of an element persists even for amounts less than 0 0001 per cent, and thus the difficulty of identifying its lines does not increase for small concentrations to the same extent as it does for the optical spectra

Quantitative X Ray Analysis —Profs Coster and Hevesy, incidental to their discovery of the element hafnium, were the first to develop a quantitative method of X ray analysis They determined the amount of that element in a number of minerals by an empirical method in which tantalum was added to a mineral until in the spectrum of the mixture the tantalum $L\alpha_1$ line ($\lambda = 1\ 518$ A) gave the same blackening on the photographic plate as the hafnium $L\alpha_1$ line ($\lambda = 1\ 566$ A) The amount of hafnium present was taken to be equal to the amount of tantalum added

In a paper which is being published in the *Proceedings of the Royal Society*, we have described a quantitative method which gives the ratio of the amounts of the two elements present in an alloy for a wide range of values of the ratio This method is not restricted, as is that of Coster and Hevesy, to discovering when

the elements are present in equal amount, and no addition of an element to the substance to be analysed needs to be made The assumption is made that, for an alloy of two elements of nearly equal atomic number, the ratio of the number of the atoms of the two elements present is equal to the ratio of the intensities of corresponding lines (say the $K\,\alpha_1$ lines) in the spectrum of the alloy, provided these lines are excited under equivalent conditions The X ray line intensities are determined photographically by photo metering the lines, and by determining the X ray Hurter and Driffield curve of the emulsion used The determination of line intensities in this way is found to be both convenient and accurate The assumption mentioned has been verified to a quite satisfactory degree of accuracy by making an X ray analysis of the following six alloys of known composition

Cu 73 per cent, Zn 27 per cent, Cu 1 1, Zn 98 9, Cu 0 11, Zn 99 89, Sn 71, Cd 29, Pb 60 5, Bi 39 5, and 12 per cent Zn in Zn-Sn Cu

The alloys used included both heterogeneous and homogeneous structures, and in some cases the K series was used, in others the L series

Our observations are not in agreement with those of previous workers in respect to the effect of a third element, an effect referred to by Prof Hevesy Coster and Nishina found that the presence of a third element in a powder mixture affected the accuracy of their results in cases when no selective absorption took place, and they concluded that the same method as we have used was not accurate For alloys, however, we find it quite accurate

Nature of the Magnetisation Curve of Single Iron Crystals.

IN recent years various observers have investigated the magnetisation of single iron crystals Their results differ in several important respects From investigations of iron crystals made in these laboratories, we believe that the observed differences are ascribable mainly to the unsatisfactory accuracy with which magnetic field intensity has been estimated when the demagnetisation factor is very large, or when it is a function of the magnetisation, as it is in specimens that are not ellipsoids In the latter case, the only way in which the field intensity can be determined is by direct measurement Experimenters, strangely enough, have seldom employed this procedure, preferring rather to rely on calculation of the demagnetising component of the field intensity by methods which have been shown to rest on invalid assumptions

The outstanding problem evoked by these discrepant observations is the question of whether or not there are 'breaks' (abrupt changes of slope) in the magnetisation curves and hysteresis loops The existence of this phenomenon was announced by W Gerlach (*Phys Zeits*, **26**, 914, 1925) four years ago. Since then its reality has been repeatedly confirmed or denied by other observers

We believe that the breaks appearing in these curves are spurious, and that in the few cases where it is not possible to draw a smooth curve fitting the points equally well, they are due to incorrect estimation of the field intensities In support of this idea we offer the following facts:

When a sufficient number of points on the curve are obtained and the *actual* magnetising field—the applied field less the demagnetising component—is *measured* with considerable accuracy, the magnetisation curve has no breaks (Foster, *Phys Rev*, **33**, 1071, 1929) If, however, these same data are plotted *without* applying the measured field intensity corrections, curves are obtained which in most cases are so flattened at the knee that it is possible to construct that portion of the curve with one or two sharp changes of slope The reason for this is that the demagnetising component of the field intensity usually goes through a rather sharp maximum in the same range of magnetisation as is occupied by the knee of the curve This maximum is always present in uniform cylinders In iron crystals the curve of demagnetising component vs magnetisation, or 'correction curve', is unlike that for ordinary iron, and is similar in shape to that obtained in poly crystalline permalloy (Foster, *Phil Mag*, **8**, 312, 1929) In no case is this correction curve the familiar straight line ('shearing curve') which has been so generally assumed

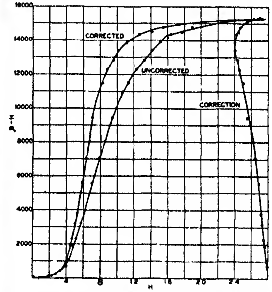

FIG 1 —Magnetisation curve of an iron crystal showing the characteristic correction curve and the effect of omitting it

There have been three other researches in which the intensity of the actual magnetising field was measured In two cases (Dussler and Gerlach, *Zeits f Physik*, **44**, 279, 1927, Gries and Esser, *Archiv f Elektrotech*, **22**, 145, 1929) the authors show curves with breaks, but there are not enough points in the region in question to justify them In the third (Wolman, *Archiv f Elektrotech*, **19**, 385, 1928) the published curves are smooth Sizoo (*Zeits f Physik*, **56**, 649, 1929), whose specimens were cylinders with rounded ends, regards the fact that his uncorrected curve is broken as proof that the true curve must be regarded as a broken one Our determination of the actual field corrections for cylindrical iron crystals indicates that only the uncorrected curve is flattened at the knee The explanation of the breaks is illustrated in Fig 1

Atmospheric Light Columns from Artificial Lights.

Brilliant beams of light, appearing to go upwards vertically from street lamps and electric signs, are seen here frequently during the winter months The accompanying photograph (Fig 1), taken on the evening of Feb 4, shows a typical case

The beams are seen only when the air is filled with snow or ice crystals These apparently act as reflectors, since the beams from neon signs show the same colour red as the source itself Examination of the beams through a Nicol prism indicates that they are unpolarised

An exceptional case was observed on the evening of Jan 3 A powerful electric sign showed four beams in addition to the vertical beam Two of

Fig 1

these were horizontal, while the other two were inclined at an angle of about 45° with the horizontal The horizontal beams were apparently of the same intensity as the vertical beam The inclined beams were just visible

Up to the present I have been unable to find a mention of this phenomena in the literature on the subject, or to suggest a reasonable explanation

B W Currie
University of Saskatchewan,
Saskatoon, Sask, Feb. 8

Light columns over artificial lights have been described previously, but Mr Currie appears to be the first to photograph the phenomenon

The columns can be explained in the same way as sun pillars Mr Currie suggests that the light is reflected from the surfaces of ice crystals We may add that to produce vertical columns the reflecting surfaces must be nearly horizontal The effective crystals are probably laminar A flat disc falling slowly through the air keeps nearly horizontal.

In the explanation of the sun pillar, stress has to be laid on the fact that the falling disc will wobble or even spin so that the reflecting surfaces are not strictly horizontal and the pillar is analogous to the streak of light produced by reflection from rippled water Columns such as are shown in Fig 1 might be due, however, to reflection from strictly horizontal surfaces at different heights in the atmosphere The elevation of the tallest of the columns may be estimated at about 12° If the source of this light was a mile from the camera, reflection from a horizontal surface at a height of 500 feet would serve to produce rays coming down at that angle. The narrowness of the beams is in favour of this view of the phenomenon

As to the exceptional observation of Jan 3, it is likely that crystals of two types were present, laminar crystals were responsible for the vertical column On the analogy of the mock sun ring, the horizontal beams must have been due to the reflection of light from the faces of prisms floating with their axes vertical Two reasons for the assumption of this position are known Either the crystals contain air bubbles or they have flat crystals attached to them to serve as parachutes The latter explanation is the more likely in the present instance, for flat crystals were certainly present, and it is known that prisms can grow on the under sides of flat crystals

The beams inclined at 45° have no analogue in daylight observations Such beams might be due to light reflected twice, once at a vertical surface and once at a horizontal surface

The growth of brilliant illumination in the cities of the north will provide an opportunity for the observation of various other phenomena If an artificial mock-sun ring can be seen, the mock suns themselves should be looked for as well as the circular halo Mr Currie is to be congratulated on his pioneer work in this field The suggestion may be added that when possible the *forms* of the crystals should be recorded as well as the optical phenomena attributed to their presence

The Heat of Dissociation of Oxygen and of the C-H Bond.

In a short notice in *Die Naturwissenschaften*, Dec 20, 1929, I published a new method of determining the heat of dissociation of oxygen (128 kcal), comparing the spectroscopical dissociation of nitrogen peroxide with the thermal decomposition according to the scheme

$$\begin{array}{ll} \text{Photochemical} & NO_2 = NO + O - 77 \text{ kcal } (\lambda 3700) \\ \text{Thermal} & NO_2 = NO + \tfrac{1}{2}O_2 - 13 \text{ kcal} \end{array}$$

In a letter in Nature of Feb 8, p 202, Prof. V Henri has calculated—using exactly the same method and values adopted by me in my note—this heat of dissociation, and arrives, of course, at exactly the same value of 128 kcal It should be stated here that my computation of the dissociation energy was based not only on the fine work of Norrish on the photochemical decomposition of nitrogen peroxide but also on my own spectroscopical investigations of the absorption spectrum of this molecule. I found that predissociation took place between λ3700 and λ3800 A A full account of this new method of determining spectroscopically heats of dissociation was given at the meeting of the Physikalische Gesellschaft at Kreuznach on Nov. 23, 1929, and will be published in *Zeits f phys Chemie* (B)

I would especially wish to emphasise here that my method may readily be extended to other problems. From the thermal decomposition of ozone according to the analogous scheme

$$\begin{array}{ll} \text{Photochemical} & O_3 = O_2 + O - 30 \text{ kcal. } (\lambda 9500) \\ \text{Thermal} & O_3 = O_2 + \tfrac{1}{2}O_2 + 34 \text{ kcal.} \end{array}$$

it follows that photochemical decomposition should start at about λ9500 if the dissociation products are normal O_2 and normal O, or at about λ4100 or less, if some excited molecule or atom is the end product.

On the other hand, the photochemical formation of ozone will start first at λ2200, since the existence of oxygen atoms is required for this reaction Decomposition of ozone was found at λ6000 (Kistiakowski) and λ4360 (Bonhoeffer) and formation at λ2070 (Warburg) in agreement with the above statement

In the same way the energies of different C H bonds in hydrocarbon compounds might be determined, for example (formaldehyde)

Photochemical	$H_2CO = HCO + H - 107$ kcal	(Predissociation at λ2670)
Thermal	$H_2CO = CO + H_2 - 2$	(calc from heat of combustion)
	$H_2 = 2H - 101$	
	$HCO = CO + H + 4$ kcal (!)	

The energy of the C H bond in formaldehyde is 107 kcal (acetaldehyde 93 kcal, benzaldehyde 110 kcal — predissociation at λ3050 and λ2550 according to V Henri and S A Schou) Therefore it requires 111 kcal to excite normal (bivalent) carbon monoxide to the tetravalent $=C=O$ molecule, which is responsible for the reaction The same value is obtained from the dissociation of carbon dioxide The energy of the CO bond, derived from spectroscopical data, is about 240 kcal (not very accurately known), whilst the decomposition of carbon dioxide into normal carbon monoxide and oxygen requires only 130 kcal, so that the excitation energy is about 110 kcal

Assuming this value, derived independently from two reactions, to be correct, one is able to calculate the energy of the CH bond in methane to be 115 kcal and that of the C C bond in different hydrocarbon compounds to be 110 115 kcal, compared with the old values of 90 kcal (CH) and 65 kcal (C C) The energies of the $C=C$ and $C\equiv C$ bonds come out to be about 200 and 300 kcal

Sex in Fungi.

In their letter in Nature of Mar 1, Prof R Ruggles Gates and D V Daran appear to welcome the new views on heterothallism in the fungi, such as Dame Helen Gwynne Vaughan's conception of nutritive heterothallism, which have come in, as they say, "to relieve the tension on the earlier rigid hypothesis of fixed + and − strains corresponding respectively to the female and the male sex"

It is only fair to point out that Dame Helen Gwynne-Vaughan and her colleague, Mrs H S Williamson, only put forward this suggestion of nutritive heterothallism tentatively and frankly admit that "we have not yet been able to justify this term"

To interpret the various forms of heterothallism found in the fungi, the facts discovered in recent years must be fully realised Sex heterothallism is only one of several forms of heterothallism, and it is perhaps due to the confusion between these various forms that the theory of multiple sexes has gained such a hold A much simpler and more workable hypothesis, as pointed out by Brunswik, is the conception of two sexes, the inter reactions between them being controlled by one or more factors other than sex factors These controlling factors are held by Kniep to be positive sex factors, by Brunswik to be negative sterility factors, and, as the latter also points out, the conception of one or more sterility factors eliminates the necessity (on the positive sex factor hypothesis) for the assumption of multiple allelomorphism (to the nth) to account for the complete fertility between geographical races, as found in some of the Coprini But a corollary must be added to Brunswik's hypothesis Since, in a number of cases of Coprini, all the mycelia of one fruiting body will show complete fertility towards all the mycelia of another fruiting body, the mycelia must be potentially bi sexual, although haploid, and the lack of fusion between certain given mycelia from the *same* fruiting body is due to the effect produced by one self sterility factor, or by certain given combinations of two self sterility factors

The work on *Humaria granulata* has thrown a flood of light on this problem Here we have a fungus in which the mono ascospore mycelia are to all appearances female, the first case of the kind to be recorded When grown singly the mycelia remain sterile, when combined with each other, half the combinations prove fertile The authors rightly point out that this is not sex heterothallism (haplo synœcism) If it is a case of nutritive heterothallism, then a further assumption has to be made, to explain the fact that only half the combinations are fertile

Thus two entirely new assumptions have to be made which only add to the complexity of heterothallism in the fungi of which Prof Gates and Mr Daran complain

The results, however, can be explained adequately in another way, without either of these assumptions, as follows

The mycelia must be self sterile, and although haploid must be potentially bi sexual They fall into two definite groups, in the ratio of 1 1, and the members of each group are sterile *inter se* This sterility can be explained on the basis of one self sterility factor *Aa* This factor and its allelomorph would segregate at meiosis in the ascus, so that half the spores would receive *A*, and the other half *a* As like will not fuse with like, mycelia carrying *A* will only fuse with *a*, and the only possible zygote is *Aa* On this assumption the mono ascospore mycelia from such a zygote would be of two kinds and would give 50 per cent of fertile combinations

This is not sex heterothallism but a form of physiological heterothallism based on one self sterility factor in a haplo synœcious fungus

The same interpretation might be applied to the heterothallic Hymonomycetes, haplo synœcism with one self sterility factor in the species showing bi polar segregation, and two self sterility factors in the quadri polar species

The results of the experiments on *Humaria granulata* tend to strengthen the evidence in favour of the conception of only two sexes in the fungi, and the occurrence of other factors which disturb their inter-reactions

With regard to the results of the experiments on the heterothallic *Mucor hiemalis* (a species showing true haplo heterœcism), it is not quite clear whether it is to be inferred that they bear upon the subject of nutritive heterothallism or not The striking morphological and physiological changes induced by subjecting the mycelia to adverse conditions are interesting, but although zygospore formation may be completely inhibited, there is no evidence of nutritive heterothallism, and the repulsion shown by the mycelia of both strains suggests some form of staling. Neither does the production of imperfect zygospores support this view, as the formation of abortive fruiting bodies is not uncommon in the heterothallic fungi In the Hymenomycetes, some strains are even capable of producing haploid fruiting bodies with viable spores, but these spores are all of the same sex (so called)

Merton Park, S W 19, Mar. 6.

Projection of Long Spark upon the Yellow Spot of the Retina

The entopic vision of the fovea centralis by an instantaneous illumination, especially by blue light, may be well known to ophthalmologists The following observations, which were made during our physical experiments with long disruptive sparks of a characteristic type, may, however, be of some special interest

A fine straight spark of several centimetres may be produced between two spherical electrodes of 3 5 cm diameter which are continuously charged up by means of a Wommelsdorf machine with about 1 m capacity in parallel, provided that a needle point leakage is attached to the positive lead at a point not too near the spark gap With this arrangement the usual irregular bending of spark tracks is effectively avoided, and nearly straight long sparks may be drawn successively at regular intervals By projecting the magnified image of this spark on a ground glass screen by means of a proper photographic lens, we obtain a fine luminous line of considerable length and of extremely short duration, which appears at the same position of the screen in regular succession This constancy of spark track can only be obtained with the use of the needle above mentioned

It is this type of spark which is specially suited for the observation of the physiological effect here in question Place a blue filter glass in front of the photographic lens, or before the eye, and look at the image of the spark from a suitable distance Using a single eye adapted to darkness for a sufficient time, the part of the luminous line corresponding to the foveal region appears very dark and of saturated blue colour The dark segment seems to make a singular jerky motion, spreading out a little on both sides This motion can be seen better when a short segment of the spark is observed, screening off the remaining part by an opaque sheet On looking at a point on the immediate outside of one end of the luminous streak, luminosity seems to move towards the other end Some observers seem to perceive also a momentary contracting motion of the dark segment at the beginning or the end of the expanding motion

Outside the foveal region the luminosity appears to move towards the yellow spot This may be observed most effectively when the eye is fixed at a point outside one end of the long spark image

Another fact which may perhaps be of special interest is that when the image of the spark is thrown across the centre of the foveal region we may observe a pair of faint circular haloes on the two sides of the spark track The interior of the halo is quite dark and the two dark discs touch the spark as well as each other The screen was covered by a piece of cardboard with a slit slightly wider than the spark image, such that the faint illumination of the general background in the neighbourhood of the spark could be cut off The halo remained This is probably brought about by the propagation of excitation along the marginal part of the fovea centralis

With a yellow filter, the foveal part appears brighter than the external part and bounded by dark fringes

The experiments may be varied widely by altering the intensity and magnification of spark, the distance of the eye from the screen, the time interval of successive sparks, the time of adaptation of the eye to darkness, etc

The visual angle of the foveal dark segment was measured and found to be considerably different for two observers

The Absorption Spectrum of Selenium Dioxide.

The fact that selenium dioxide, a white solid, gives a brown vapour has been discussed by Meyer and Langner (*Ber*, 60 B, 285, 1927), who conclude that the colour must be due to the dioxide and cannot be attributed to selenium liberated by dissociation

The absorption spectrum of selenium dioxide has been partially described in a brief note by E J Evans and G N Antonoff (*Astrophys Jour*, 34, 277, 1911), who, using 0 006 gm of the material in an evacuated tube at temperatures ranging from 360° to 900° C, observed absorption band heads from λλ3930 to 4470 A and, at the highest temperature, continuous absorption below λ4200 A But absorption in this region will not account for the brown colour of the vapour, which is observed, moreover, at temperatures of the order of 300° 400° C The spectrum has now been photographed in this laboratory on a Hilger E 1 quartz spectrograph and banded structure has been found to extend over a much wider range, namely, λλ3840 to 5740 A

Evans and Antonoff's result may be due to the selenium dioxide vapour in the tube not being saturated, and further to the fact that selenium dioxide dissociates rapidly *in vacuo* For this reason, in the present work excess of selenium dioxide was taken and the tube filled with oxygen at a pressure of half an atmosphere at room temperature before sealing off

The pyrex absorption tube was 1½ metres long and was heated electrically to temperatures ranging from 250° to 400° C according to the region of the spectrum it was desired to observe I am indebted to Mr T W Parker, of the Chemistry Department of this College, for a supply of freshly prepared selenium dioxide

In the near ultra violet and violet a regular series of diffuse heads is observed, some of which have an appearance of a very complex and fine structure The diffuseness may thus be due to insufficient resolving power In the blue green, green and yellow, the obvious regularity disappears, but there are a number of sharp heads, degraded to the red

This spectrum is presumably due to selenium dioxide, since saturated selenium vapour at a temperature of the order of 400° C, in a similar tube, was found to give no absorption in the region in question Evans and Antonoff obtained selenium absorption bands in this region, but at a higher temperature at 300° C, absorption was confined to the region λλ3200 3700 Further, when an evacuated absorption tube was used in the present work, the spectrum gradually disappeared owing to the dissociation of the selenium dioxide

The wave lengths of the band heads are now being measured, and it is hoped to give fuller details elsewhere

Dissociation Energy of Zn_2 Molecules

It has been shown by me (*Zeits f Phys*, 55, 338, 1929) that the dissociation energy of Hg_2 molecules is greater than has been supposed Also, for Cd_2 molecules several optical data show that we have to deal with high dissociation energy (23 kcal /mol given by Jablonski) The dissociation energy of Zn_2 molecules found by Winans cannot be considered as probable, because Jablonski and Kapuscinski have shown that the considerations of Winans led to erroneous value for the dissociation energy of Cd_2 molecules Therefore it seems interesting to make

direct measurement of the evaporation energy of Zn_2 molecules This last value was found from changes of the band absorption coefficient to be dependent upon the temperature of saturated zinc vapour Preliminary microphotometric measurements of photographic plate density were made for three wave lengths, 2313, 2502 and 2558 A for the range of temperatures 790°–920° C The results of calculations give a number of values which do not differ more than 3 kcal /mol from the average value 32 kcal mol It is thus possible to give in a table a comparison of energies of evaporation of atoms (1), of corresponding molecules (2) and their dissociation energies (3), for three elements—zinc, cadmium, and mercury (in kcal /mol)

	1	2	3
Zinc	30 5	32	29
Cadmium	26 5	30	23
Mercury	14 5	11	18

The value of evaporation energy of Hg_2 molecules was given by me in a former paper (l c), the dissociation energy of Zn_2 and Hg_2 molecules results from the corresponding evaporation energies of atoms and molecules, the value of evaporation energy of Cd_2 molecules were found by putting for the dissociation energy the value given by Jablonski

These results show that the absorption band system of zinc vapour found by Mohler and Moore in the wave length range 2636–2551 A corresponds to the $2^3P\ 1^1S_0$ atom transition For the author found the continuation of this band system in the directions of shorter and longer wave lengths, the limit of convergence of these bands corresponds sufficiently well to the calculated dissociation energy of Zn_2 molecules

Electronic Fine Structure in Helium Bands

EXPERIMENTAL evidence for the triplet nature of the $2\pi^3\Pi_g$ and $2\pi^3\Pi_u$ terms of the helium molecule has recently been given by Prof Mulliken and Dr Monk

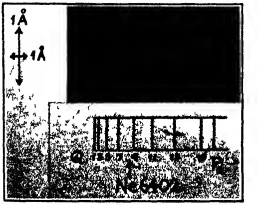

FIG 1.

with their grating spectrograms of the band 6400 A (*Phys Rev*, 34, 1530, 1929) The resolution into doublets (two of the triplet components being too near to be resolved) is more clearly shown on our interference spectrogram of the same band (Fig 1) The photograph was taken by projecting horizontal fringes formed by a 40 plate echelon (resolving power, c 400,000) on to the fairly wide slit of a plane grating spectrograph, the latter giving a dispersion of 3 2 A per mm in the first order The exposure was one hour The neon (impurity) line 6402 246 A served as the standard of measurements, as this line appears in two consecutive orders, their distance $\Delta\lambda_{max}$ being 0 64057 A

The measured doublet separations are

BAND 6400 A

Line	Q_1	Q_3	Q_5	Q_7	Q_9	Q_{11}	Q_{13}	Q_{15}
$\Delta\lambda$ (A)	0 145	0 115	0 119	0 114	0 109	0 111	0 10	0 08
$\Delta\nu$ (cm $^{-1}$)	0 354	0 281	0 290	0 278	0 266	0 271	0·24	0 21

Line	P_2
$\Delta\lambda$ (A)	0 110
$\Delta\nu_b$ (cm $^{-1}$)	0 268

Further investigation on this and other helium bands, using a tube cooled with liquid air, is in progress

Coloured Glass as a Deterrent to House Flies

SOME years ago Messrs W P Hartley, Ltd , jam manufacturers, Aintree, glazed their storage warehouses with yellow glass The warehouses are connected by corridors which were glazed with ordinary glass They noticed that whereas there were always plenty of flies in the corridors these never went into the warehouses They then glazed the corridors with yellow glass, and found that they got rid of the flies from these also

We have heard of other instances where coloured glasses have been used as a deterrent for flies, and we understand that some abattoirs have been glazed with blue glass

As we were continually being asked for advice on this subject, we decided to carry out some experiments in an endeavour to ascertain whether the house fly was susceptible to coloured light, and if so, which colour was the best deterrent We carried out a series of experiments last summer under advice from Prof R Newstead, and found that, everything else being equal, the house fly prefers white light to coloured light, and that red and yellow are the best deterrents Blue and green are not nearly so effective The loss in illumination with red glass being too great for general use, it appears that yellow is the best

Although it cannot be claimed that the use of yellow glass is an absolute preventive, it is a very effective deterrent, and valuable for use in connexion with the storage of food

We do not suggest the use of yellow glass for any building in which people are continually employed, because it has been found that yellow light is bad for the eyes and general health

We cannot find a record of any work on this subject, and intend to continue our experiments during the coming summer In the meantime we wonder whether any readers of NATURE have noticed this peculiar attitude of the house fly towards coloured light, and can offer any explanation

Radio Direction-Finding by Transmission and Reception.*

By Dr R L Smith-Rose

THE application of the rotating closed loop direction finder, both as a navigational instrument and as a useful scientific tool in the study of the propagation of electro magnetic waves, has been developing rapidly during the past few years So long ago as 1901 the performance of a direction finder was being studied in America, but owing to its comparative insensitiveness as a receiver the modern radio direction finder owes its success very largely to the introduction of valve amplifiers, which enabled a moderately large reception range to be obtained The practical development of the instrument, therefore, dates from about 1915

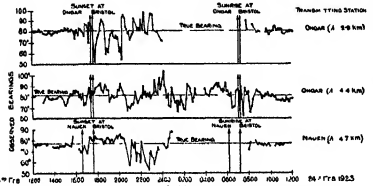

Fig 1 —Graphs of observed bearings of Ongar (undamped waves λ = 2 9 km and 4 4 km) and Nauen (undamped waves, λ = 4 7 km) taken at Bristol over a 24 hour period

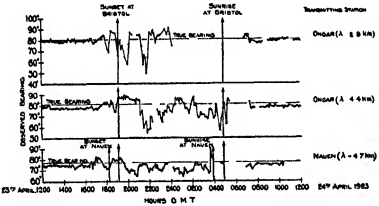

Fig 2 —Graphs of observed bearings of Ongar (undamped waves λ = 2 9 km and 4 4 km) and Nauen (λ = 4 7 km) taken at Bristol over a 24 hour period

The Radio Direction Finder

The several commercial types of direction finder now in use employ the same fundamental principle of the reception of vertically polarised † wireless waves by a closed coil In the attachment of a valve amplifying receiver to the rotating closed coil, the possibility of obtaining spurious electromotive forces in the system is introduced on account of the phenomena generally known as the 'antenna effect' of the coil and the 'direct pick up' of signal electromotive force on various parts of the receiver These spurious electromotive forces make themselves evident by a blurring of the signal zeros, with or without a displacement of these zeros from their correct positions The methods adopted for overcoming these effects are based upon the use of somewhat elaborate screening arrangements, which were employed in the first place in the construction of direction finders for accurate research purposes but are now being applied to commercial instruments In the commercial pattern of rotating loop marine direction finder, the receiving coil is enclosed in a metallic shielding tube mounted on a robust column on the deck above the operating room, in which the rotation of the loop and all receiving adjustments can be effected when it is desired to make bearing observations upon any incoming signals In the case of such use of a direction finder on board ship, the bearing is taken relative to the ship's head, and it is necessary to obtain this direct from the compass reading in order to make the wireless bearing refer to a great circle direction

Before the development of valve amplifiers made possible the use of rotatable multi turn loops, Artom, Bellini, and Tosi suggested and used large frames of a triangular shape for directional wireless communication The large fixed loops employed in this arrangement, now generally known as the Bellini Tosi system, are connected to a radiogoniometer, an instrument which reproduces in miniature the directive properties of the external field of the waves Recent developments of this system for use in ships have resulted in the employment of smaller multi turn loops which are more conveniently fixed on board and are shielded in a manner similar to the single loops referred to above

In the application of a direction-finding system to either marine or aerial navigation, it is important to understand clearly the exact conditions under which the observed bearings are accurate, and in other conditions to appreciate the order of magnitude of the possible errors involved and the means of mitigating these where possible An important factor to be noted from a navigational

* Abstract of a lecture delivered at the Royal Institution on Feb 6

† The term 'vertically polarised' is used here to indicate that the electric force of the wave lies in the vertical plane of propagation

point of view is that of any effect of fog on direction finding, since it is generally during foggy weather that the majority of marine direction finders are called into action The experience of all observers for several years past is in agreement that the existence of fog, whether local or widespread, gives rise to no abnormal effects in direction finding

Various conditions may be present in the neighbourhood of a direction finding station to cause an error in the bearing observed on a distant transmitting station From various detailed investigations into the causes of such errors, it is known that the most prominent effects are due to masses of metal work and wires, either above or below the earth's surface and to trees In most cases where the directional station is situated on land, it is possible to select a site which is largely, if not entirely, immune from such effects In the case of the use of a direction finder on board ship, it is impossible to be clear of the metal work of the ship itself, and the resulting bearings are subject to a quadrantal error which can either be compensated by circuit adjustment or corrected for by a chart

Another type of error which is of some importance in the application of direction finding to marine navigation is that due to the deviation of wireless waves in crossing a coast line when the path of the waves lies approximately parallel to the coast On wave lengths of from 450 metres to 1000 metres, normally used for marine working, the coastal error is of the order of 2°–4° when the direction of transmission is within 20° of the coast line The error is always such as to indicate a bending of the waves towards the normal to the coast line in passing from the sea to the land side of the boundary In connexion with these coastal errors, it is worthy of note that, with the accumulation of experience of the use of direction finders on board ship, it is now becoming customary to mark out on charts the 'arcs of good bearings' of various transmitting stations within which results of observations are found to be trustworthy

As an illustration of the reliability of direction finding as applied to marine navigation, the results of some tests carried out between a direction finding station on the east coast of England and various ships crossing the North Sea may be quoted At the various ranges of transmission up to nearly 120 miles, the limiting error of the direction finder bearing was about 4° In more than 80 per cent of the cases the wireless bearings were correct to within 1°, while the proportion correct to within 2° was nearly 95 per cent These figures refer to bearings taken at a shore station on transmissions from ships across an intervening open sea path at ranges up to about 100 miles Since it is now generally agreed that an accuracy of 2° is adequate for most navigation purposes, it is evident that under its ordinary conditions of use the direction finder is a very trustworthy and useful aid to marine navigation Similar results to the above are obtainable with the direction-finder installation fitted on board ship and observations made on the transmissions from a shore station A large number of fixed beacon transmitting stations are now in operation in various parts of the world for the specific purpose of emitting a regular series of signals for the use of ships fitted with direction finders

NIGHT ERRORS

When the range of transmission is greater than the figure mentioned above the accuracy of the observed direction finder bearings is liable to de-

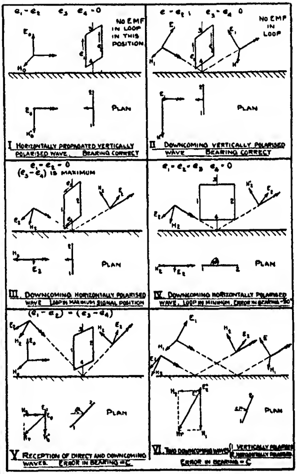

FIG 3

preciate during the hours of darkness, when some erratic variations of the observed bearings take place, accompanied by a change in quality of the signal minima The general nature of these variations can be understood from the typical graphs given in Figs 1 and 2, which show the apparent bearings of some fixed transmitting stations as observed every few minutes over periods of twenty-four hours at one observing station On the wave lengths in question, of 2000–4000 metres, it is to be noticed that the day bearings are much steadier in the summer than in the winter months, but that in either case the approach of sunset is accompanied by an increase in the magnitude and frequency of the variable errors which continues

throughout the night until sunrise Such variable errors may range up to 90° or more, but it is noteworthy that during the night periods the observed bearings show no signs of a definite systematic error, and so the variations are on the whole equally distributed about the true bearing The larger errors are also comparatively rare, in fact, observations over long periods have shown that it is seldom that more than 10 per cent of the night observations give an error exceeding 10°

The cause of the erratic effects and variations observed generally during the night periods is intimately associated with the mode of propagation of electromagnetic waves over the earth's surface This has been the subject of much detailed research during the past few years, and it is now well known that, in general, two sets of waves travel between a transmitting and receiving station—the direct or ground wave, and the indirect or atmospheric wave At short distances from the transmitter, the intensity of the indirect wave is generally small, and only the wave transmitted directly along the earth's surface is of importance in producing the received signal At medium distances, both the direct and the indirect wave are received, while at great distances the major part or the whole of the received signal is due to the indirect wave which has travelled through the upper atmosphere

In order to explain the variations in apparent bearings on the closed type of direction finder we have been considering, it is necessary to assume that the plane of polarisation of the downcoming waves may vary This is undoubtedly caused by a rotation of the plane of polarisation which takes place while the waves are travelling through the ionised regions of the atmosphere and is due to the presence of the earth's magnetic field In Fig 3, diagrammatic illustrations are given of a number of simple cases of the reception of wireless waves on a closed loop, and from these it will be seen that it is the horizontal component of the electric force of the downcoming waves which is responsible for producing an error in bearing So long as the vertically polarised direct wave is strong compared with the horizontally polarised component of the downcoming waves, the error in bearing will be small Thus the variations in bearings close to the transmitter will be small, a conclusion which is confirmed in practice, for night variations are not experienced at distances less than about 30 miles for overland working

(To be continued)

Nobel Prize Awards

FOLLOWING upon the article in our issue of Mar 29, p 495, on the history and constitution of the committees of the Nobel Foundation, we print below a complete list of the recipients since 1901—the date of the first distribution—of Nobel prizes for physics, chemistry, physiology and medicine, classified according to countries, each country representing the working domicile of the recipient at the time of allotment of the prize

Physics

Denmark

1922 Prof Niels Bohr (Copenhagen), for his services in the investigation of the structure of atoms, and of the radiation emanating from them

France

1903 Prof Henri Antoine Becquerel (Paris) In recognition of the special services rendered by him in the discovery of spontaneous radioactivity One half the prize allotted, the other half divided equally between Prof Pierre Curie (Paris) and Madame Curie, for special services rendered by them in the work they carried out jointly in investigating the phenomena of radiation discovered by Henri Becquerel

1908 Prof Gabriel Lippmann (Paris), for his method, based upon the phenomenon of interference, for reproducing colours by photography

1909 Prof Ferdinand Braun (Strasbourg), in recognition of services in the development of wireless telegraphy The prize was divided equally with G Marconi (Italy)

1920 M Charles Edouard Guillaume (Sèvres), in recognition of his services to the physics of precision by his discovery of anomalies in nickel steel alloys

1926 Prof Jean Perrin (Paris), for his works on the discontinuous structure of matter, and especially for his discovery of the equilibrium of sedimentation

1929 M Louis Victor de Broglie (Paris), for his discovery of the wave character of the electrons

Germany

1901 Prof Wilhelm Conrad Rontgen (Munich), in recognition of the exceptional services rendered by him in the discovery of the special rays which have been called after him

1905 Prof Philipp Lenard (Kiel), for his work in connexion with cathode rays

1911 Prof Wilhelm Wien (Wurzburg), for his discoveries regarding the laws governing the radiation of heat

1914 Prof Max von Laue (Frankfort on Main), for his discovery of the defraction of Röntgen rays on passing through crystals

1918 Prof Max Planck (Berlin), for his discoveries in connexion with the quantum theory Awarded in 1919

1919 Prof Johannes Stark (Greifswald), for his discovery of the Doppler effect in canal rays, and of the decomposition of spectrum lines in an electric field

1921 Prof Albert Einstein (Berlin), for his services to the theory of physics, and especially for his discovery of the law of the photo-electric effect

1925 Prof James Franck (Göttingen), and Prof Gustav Hertz (Halle), for their discovery of the laws governing the impact of an electron upon an atom The prize was divided equally in 1926.

GREAT BRITAIN

1904 Lord Rayleigh, for his investigations into the density of the most important gases, and for his discovery of argon in connexion with these investigations

1906 Prof Joseph John Thomson, in recognition of the great services rendered by him in his theoretic and experimental investigations regarding the passage of electricity through gases

1915 Prof William Henry Bragg and Prof William Lawrence Bragg, for their services in the analysis of crystal structure, by means of X rays The prize was divided equally

1917 Prof Charles Glover Barkla, for his discovery of the characteristic Röntgen radiation of the elements Awarded in 1918

1927 Prof Charles Thomson Rees Wilson, for the method discovered by him of perceiving by condensation of steam the paths taken by electrically charged particles The prize for this year was divided equally with Prof A H Compton (United States)

1928 Prof Owen Willans Richardson, for his researches upon the thermionic phenomenon, and especially for his discovery of the law named after him Awarded in 1929

ITALY

1909 Guglielmo Marconi (born Bologna), in recognition of services in the development of wireless telegraphy The prize was divided equally with Prof Ferdinand Braun (Strasbourg)

NETHERLANDS

1902 Prof Hendrik Antoon Lorentz (Leyden), and Prof Pieter Zeeman (Amsterdam), in recognition of the special services rendered by them in their investigations regarding the influence of magnetism upon the phenomena of radiation The prize was divided equally

1910 Johannes Diederik van der Waals (formerly at Amsterdam), for his work in connexion with the equation of state for gases and liquids

1913 Prof Heike Kamerlingh Onnes (Leyden), in recognition of his investigation into the properties of matter at low temperatures which led, amongst other things, to the production of liquid helium

SWEDEN

1912 Gustaf Dalén (Stockholm), for his discovery of automatic regulators, which can be used in conjunction with gas accumulators for lighting lighthouses and light buoys

1924 Prof Karl Manne Georg Siegbahn (Uppsala), for his discoveries and investigations in X ray spectroscopy Awarded in 1925

UNITED STATES

1907 Prof Albert Abraham Michelson (Chicago), for his optical instruments of precision, and the spectroscopic and metrologic investigations which he carried out by means of them

1923 Prof Robert Andrews Millikan (Pasadena, California), for his works on the elementary charge of electricity, and on photoelectric phenomena.

1927 Prof Arthur Holly Compton (Chicago), for his discovery of the phenomenon known by his name The prize for the year was divided equally with Prof C T R Wilson (Great Britain)

The prize for physics for the year 1916 was allocated to the Special Fund for this section

Chemistry

AUSTRIA

1923 Prof Fritz Pregl (Gratz), for the method of micro analysis of organic substances discovered by him

FRANCE

1906 Prof Henri Moissan (Paris), in recognition of the great services rendered by him in his investigation and isolation of the element fluorine, as well as by his introduction to the service of science of the electric furnace called after him

1911 Prof Marie Skledowska Curie (Paris), in recognition of the services rendered by her to the development of chemistry, by her discovery of the elements radium and polonium, by her determination of the nature of radium, and isolation of it in a metallic state, and by her investigations into the compounds of this remarkable element

1912 Prof Victor Grignard (Nancy), for the so called Grignard reagent, discovered by him, which in recent years has greatly advanced the progress of organic chemistry The prize was divided equally with Prof P Sabatier

Prof Paul Sabatier (Toulouse), for his method of hydrogenating organic compounds in the presence of finely disintegrated metals, whereby the progress of organic chemistry has been greatly advanced in recent years

GERMANY

1901 Prof Jacobus Hendrik van 't Hoff (Berlin), in recognition of his special services in connexion with the discovery of the laws of chemical dynamics and osmotic pressure in solutions

1902 Prof Emil Fischer (Berlin), in recognition of his special services in connexion with his synthetic experiments in the sugar and purin groups of substances

1905 Prof Adolf von Baeyer (Munich), in recognition of his services in the development of organic chemistry and chemical industry, through his work on organic dyes and hydro aromatic combinations

1907 Prof Eduard Buchner (Berlin), in recognition of his investigations in biological chemistry and his discovery of cell less fermentation

1909 Prof Wilhelm Ostwald (Leipzig), in recognition of his works on catalysis, as well as for his investigations into the fundamental principles governing chemical equilibrium and rates of reaction

1910 Prof Otto Wallach (Göttingen), in recognition of the services rendered by him to organic chemistry and the chemical industry, through his pioneer work in the field of alicyclic compounds

1915. Prof Richard Willstätter (Munich), for his researches into the colouring matter of plants, especially chlorophyll

1918 Prof Fritz Haber (Berlin-Dahlem), for

the synthetic production of ammonia from its elements Awarded in 1919

1920 Prof Walther Nernst (Berlin), in recognition of his work in thermo chemistry Awarded in 1921

1925 Prof Richard Zsigmondy (Göttingen), for his exposition of the heterogeneous nature of colloid solutions, and for the methods he used in that connexion, which have become a determining factor in the modern chemistry of colloids Awarded in 1926

1927 Prof Heinrich Wieland (Munich), for his investigations into the constitution of the bile acids and kindred substances Awarded in 1928

1928 Prof Adolf Windaus (Göttingen), for his services in the investigation of the constitution of the sterols and their connexion with the vitamins

Great Britain

1904 Sir William Ramsay, in recognition of his services in the discovery of the inert gaseous elements in air, and the determination of their place in the periodic system

1908 Prof Ernest Rutherford, for his investigations into the disintegration of elements, and the chemistry of radioactive substances

1921 Prof Frederick Soddy, for his contributions to the chemical knowledge of radioactive substances, and his investigations into the origin and nature of isotopes Awarded in 1922

1922 Dr Francis William Aston, for his discovery of a great number of isotopes in several non radioactive elements, by means of his mass spectrograph, as well as for his discovery of the whole number rule

1929 Prof Arthur Harden, for investigations on the fermentation of sugars and of fermentative enzymes The prize was divided equally with Prof Hans von Euler Chelpin (Stockholm)

Sweden

1903 Prof Svante August Arrhenius (Stockholm), in recognition of special services rendered by him to the development of chemistry by his electrolytic theory of dissociation

1926 Prof Theodor Svedberg (Uppsala), for his works on disperse systems

1929 Prof Hans von Euler Chelpin (Stockholm), for investigations on the fermentation of sugars and of fermentative enzymes The prize was divided equally with Prof A Harden (Great Britain)

Switzerland

1913 Prof Alfred Werner (Zurich), in recognition of his works on the linking up of atoms within the molecule, whereby new light has been thrown upon older fields of research, and new fields have been opened up, especially within the realm of inorganic chemistry

United States.

1914 Prof Theodore William Richards (Harvard), in recognition of his accurate determination of the atomic weight of a large number of chemical elements Awarded in 1915

The prizes for the years 1916, 1917, 1919, and 1924 were allocated to the Special Fund for this section

Physiology and Medicine

Austria

1914 Robert Barany (Vienna), for his work on the physiology and pathology of the vestibular system The prize was awarded in 1915

1927 Prof Julius Wagner Jauregg (Vienna), for his discovery of the therapeutic value of malaria inoculation in the treatment of dementia paralytica

Belgium

1919 Prof Jules Bordet (Brussels), for his discoveries in connexion with immunity Awarded in 1920

Canada

1923 Prof Frederick Grant Banting (Toronto), and Prof John James Richard MacLeod (Toronto), jointly, for the discovery of insulin

Denmark

1903 Prof Niels Ryberg Finsen (Copenhagen), in recognition of his treatment of disease, especially *lupus vulgaris*, with concentrated light rays

1920 Prof August Krogh (Copenhagen), for his discovery of the regulation of the motor mechanism of capillaries

1926 Prof Johannes Fibiger (Copenhagen), for his discovery of the Spiroptera carcinoma Awarded in 1927

France

1907 Charles Louis Alphonse Laveran (Paris), for his work on the part played by protozoa in the generation of disease

1908 Prof Elie Metchnikoff (Paris), for work (with Prof Ehrlich) on immunity The prize was divided equally with Prof Paul Ehrlich (Frankfort on Main)

1913 Prof Charles Richet (Paris), for his work on anaphylaxy

Germany

1901 Prof Emil Adolf von Behring (Marburg), for his work on serum therapy against diphtheria

1905 Prof Robert Koch (Berlin), for his work on tuberculosis

1908 Prof Paul Ehrlich (Frankfort on Main), for work (with Prof Metchnikoff) on immunity The prize was divided equally with Prof Elie Metchnikoff (Paris)

1910 Prof Albrecht Kossel (Heidelberg), for his achievements in the chemistry of the cell, by his works on proteins, the nucleic substances included

1922 Prof Otto Meyerhof (Kiel), for his discovery of the correlation between the consumption of oxygen and the production of lactic acid in the muscles The prize for the year was divided equally in 1923 with Prof A V Hill (Great Britain)

Great Britain

1902 Sir Ronald Ross, for his work on malaria

1922 Prof Archibald Vivian Hill, for his dis-

covery relating to the heat-production of muscles The prize for the year was divided equally in 1923 with Prof O Meyerhof (Kiel)

1929 Sir Frederick Gowland Hopkins, for the discovery of growth promoting vitamins The prize was divided equally with Dr C Eijkman, Utrecht

ITALY

1906 Prof Camillo Golgi (Pavia), for work (with Prof Ramón y Cajal) on the structure of the nervous system The prize was divided equally with Prof Ramón y Cajal (Madrid)

NETHERLANDS

1924 Prof Willem Einthoven (Leyden), for his discovery of the mechanism of the electrocardiogram

1929 Dr C Eijkman (Utrecht), for the discovery of the anti-neuritic vitamin The prize was divided equally with Sir Frederick Gowland Hopkins (Great Britain)

RUSSIA

1904 Prof Ivan Petrovitch Pavlov (St Petersburg), in recognition of his work on the physiology of digestion

SPAIN

1906 Prof Santiago Ramón y Cajal (Madrid), for work (with Prof Golgi) on the structure of the nervous system The prize was divided equally with Prof Camillo Golgi (Pavia)

SWEDEN

1911 Prof Allvar Gullstrand (Uppsala), for his work on the dioptrics of the eye

SWITZERLAND

1909 Prof Theodor Kocher (Berne), for his work on the physiology, pathology, and surgery of the thyroid gland

TUNISIA

1928 Dr Charles Nicolle (Tunis), for his work on typhus exanthematicus

UNITED STATES

1912 Dr Alexis Carrel (New York), for his work on vascular ligature and on the grafting of blood vessels and organs

The prizes for the years 1915, 1916, 1917, 1918, 1921, and 1925 were allocated to the Special Fund for the section

On Founder's Day, Dec 10, the anniversary of the death of Dr Nobel, the adjudicators hand to the designated prize winners a draft on the Foundation for the amount due, together with a diploma and a medal in gold, bearing the testator's effigy on the obverse, and an emblematic design on the reverse

It is incumbent on a prize winner to give a lecture, if feasible, on the subject of the work for which the prize was awarded, within six months of the Founder's Day at which the prize was won, and to be given at Stockholm

Obituary

EDWARD CLODD

"Thou pirate nested over Alde!
Stern wrecker of the Established Faith!
From whom the parson shrinks appalled

A beacon to thy fellows, Clodd"
GEORGE MEREDITH, 1899

EDWARD CLODD was born at Margate on July 1, 1840 He died at his home, Strafford House, Aldeburgh, on Mar 16 He had been cruelly paralysed and largely deprived of his speech during nearly two years past but was otherwise mentally alert, he was overcome by a sudden attack of asthma, lasting barely a week His body was cremated, at Ipswich, on Mar 20, at the close of a short Rationalist service at which the few who remain of his old friends were mostly present His ashes are now cast into Aldeburgh Bay He seems to have passed away in full consciousness, satisfied to have made good use of his earthly heritage, free from all selfish wish on his own account—only sorry to go because he found the world so intensely interesting His great friend Hardy held this view at the end To have been with such men is to know the peace that knowledge can give

He came from the sea and the soil, the name being one of long standing in Suffolk At the time of his birth, his father was captain of a brig He was nurtured at the brink of the sea, at Aldeburgh, of which small town his parents were natives On joining his yacht, the *Lotus*, you naturally reported yourself—'Come aboard, Sir", he was so thoroughly the stocky, sturdy sailor in figure, with all the sailor's winsome ways Behind the sailor was a man of an astounding literary culture, burning with curiosity, ever seeking really to know, at heart he was both the man of letters and the scientific inquirer, a rare combination—though without technical training He was self educated in this respect and with wonderful finish His mother taught him to read, the Bible especially, to the end, he advocated its use, not in the service of dogmatic teaching but as the greatest work of literature in our language

Clodd was simply but well trained up to fifteen years of age, at the Aldeburgh Grammar School The head, Mr Buck, definitely imbued him with the love of learning, at his suggestion, in later years (1861), he was to write a guide to Aldeburgh In 1865 he produced a life of Crabbe, the Aldeburgh poet, the literary afflatus was in him from an early age He was meant for the Church but his imagination was so stirred, in 1851, by a visit to the Great Exhibition, that in 1855, like Whittington, he took his future into his own hands and went to London town, where he had an aunt and an uncle After serving in various offices, in 1862 he became a clerk in the London Joint Stock Bank, he then married Ten years later he was appointed secretary, a position he held until June 1915 Although not

built of business stuff, he was exactly fitted for this office It brought him into contact with many interesting men One instance he gave me—when Hughes, who later invented the microphone, came over from America, he called at the bank and saw Clodd, on leaving he deposited £7000 he had saved mostly from his earnings as a teacher of music This was at the time when gas was at its lowest owing to the introduction of the electric light and it was by happy investment in gas stock that Hughes was able to amass his fortune When he died he appointed Clodd his trustee Clodd was also trustee to 'Amazon' Bates and to Holman Hunt

He had two great gifts—the one to which he owed his literary success was the rare one of reading exactly Taking down any book in his library, you saw at once that it had been read word for word Passage after passage would be underlined and a multitude of cross references written in the margin Press notices and letters from the authors were to be found in most He had an astounding memory and to the last remembered what he read He was a critical master of anthropological literature

In his first London days he not only read hard but also attended sermons and lectures It was the time when scientific criticism began to stir the intellectual world and he was soon caught in the stream He early began to wear the shoes of Nonconformity loosely, they were unlatched when he wrote his "Childhood of the World" (1872) and came off altogether in writing his really daring "Jesus of Nazareth" (1880) From that time onwards, he was a declared anti clerical He was a Rationalist through intense logical study of the evidence He was stirred to write the "Childhood" by asking himself in all sincerity how and what he could safely and honestly teach his young children he soon felt obliged to depart from current practice "Jesus of Nazareth" appeared as a gift from the gods to a man like Huxley, to Ruskin it was anathema The original 'author's copy' on his shelves has in it a most remarkable set of letters received from all and sundry, including advanced clerics, giving their opinions upon the work Although he had no use for man made gods, no use for metaphysics, at heart he was deeply religious

Clodd's second gift, that which made him so loved, was his abounding genius for friendship His books soon brought him recognition but he had only to make one friend to be offered another and he never hesitated to offer himself freely, even to strangers, if he wished to know them His Aldeburgh home became a magnetic centre to men of distinction in every walk, excepting politics and the church

His "Memories" (1916) gives some picture of the variety of Clodd's friendships Hardy and Meredith were among them, he had author's copies of many of their works Not a little of the delight of his week ends was derived from excursions on the Alde in *Lotus* I and II—a small sturdy vessel built much upon his own lines, which sailed almost as close to the wind as he did to dogmatists and doctrine-mongers I was out with him on his last cruise, two years ago I shall never forget two occasions when his great friend Sir Mortimer Durand was our only companion Of course we discussed far Cashmere and Persia On one of these, a violent thunderstorm, which forced us to down all sail until the clouds rolled by, brought us close to the inner meaning of things as we now are by the life of a man like Edward Clodd, verily of the salt of the earth He seemed to have no original genius, yet an innate gift of using knowledge to the full Is it not time that we followed the great example of scientific service that he has set and made our knowledge of more avail? Relatively, to-day, there is great over production of knowledge, great under production of users of knowledge on the public behalf

Henry E Armstrong

Clodd was one of those numerous business men in whom Great Britain may justly pride itself, who devote their leisure to scientific and literary pursuits During forty three years he was secretary of the London Joint Stock Bank, but found time to read widely in science and literature, and being endowed with a notable gift of friendship, he became the friend of such diverse people, to name only a few, as T H Huxley, Sir William Huggins, R A Proctor, H W Bates, Joseph Thomson, Paul du Chaillu, Edward Whymper, Sir Alfred Lyall, J Cotter Morison, F York Powell, George Meredith, W Holman Hunt, Andrew Lang, Samuel Butler, Thomas Hardy

When "The Origin of Species" was published, Clodd was an ardent and inquiring young man of twenty, and the discussions which arose interested him keenly, the publication of "Essays and Reviews", followed ten years later by "Primitive Culture", together with wider reading, finally emancipated him from the strict orthodoxy in which he had been brought up Owing to the absence of a book suitable for the young on the story of man's progress, Clodd wrote "The Childhood of the World a Simple Account of Man's Origin and Early History" (1873) which has gone through numerous editions and been translated into many European languages and even into Becowana and Secwana It is impossible to estimate what effect this lucid and charming presentation of 'the new learning' had in Europe and America The polemics of the mighty were thus made easily understandable, and the young were made aware of the trend of modern thought in a manner that must have influenced their outlook on life

Two years later "The Childhood of Religion" inevitably followed, and also had a great sale Here Clodd was treading on more debatable ground, but the spirit in which it was written is admirable, though it doubtless alarmed some readers "The Story of Creation a Plain Account of Evolution" appeared in 1888 and rapidly went through many editions, and it also must have considerably, if unconsciously, affected the rising generation In 1895 followed "A Primer of Evolution" and "The Story of Primitive Man". "Pioneers of Evolution

from Thales to Huxley", in 1897, was the last of his popular expositions of evolution

Clodd was from its early days an active member of the Folk Lore Society, of which he was president in 1895 and 1896 Besides his two presidential addresses, he made various contributions to the Society's journal In 1885 he published "Myths and Dreams", and in 1898, "Tom Tit Tot, an Essay on Savage Philosophy in Folk lore", which is a delightful example of one aspect of the study of folk lore A compact little book, "Animism the Seed of Religion", appeared in 1905, and "Magic in Names and in other Things" in 1920, this is the most elaborate of Clodd's writings on folk belief and is as vividly written as his other books

In 1892, Clodd published a memoir of H W Bates in "The Naturalist on the River Amazons", in 1900 one on "Grant Allen", and in 1902 another on "Thomas Henry Huxley" In 1916 he de lighted his numerous friends with the publication of "Memories", and those who desire to know what Clodd was to his friends should read this book and incidentally they will discover what manner of man he himself was

The above list of some of his books, and his very numerous contributions to journals of all kinds, indicate that Clodd was a sower of the seed of intellectual freedom and a populariser of evolution, more particularly as regards man This is not the place to refer to his many literary associations, but no mention of Clodd would be complete without allusion to the stimulating quality of his conversation and to the notable gatherings at his home, where men of varied experience, activities, and research interchanged serious talk enlivened by jest Clodd was a perfect host, and not least so when as skipper he took his party for cruises in the *Lotus* We have lost a great friend, and we offer our heartfelt sympathy to his devoted wife, who made his declining years so happy

A C HADDON

WE regret to announce the following deaths

Prof J O Arnold, emeritus professor and lately dean of the Faculty of Metallurgy in the University of Sheffield, on Mar 24 aged seventy two years

Dr Wilhelm Biedermann, formerly professor of physiology in the University of Jena, on Nov 27, aged seventy five years

Sir Edward Brabrook, C B, a past president of the Royal Anthropological Institute and of Section H (Anthropology) and also of Section F (Economic Science and Statistics) of the British Association, on Mar 20 aged ninety years

Dr Hermann von Ihering, honorary professor of palæontology at Göttingen, for many years director of the Museu Paulista at São Paulo, Brazil, who was well known for his studies in zoo geography, the palæontology and fauna of Brazil, and the morphology and classification of the Mollusca, on Feb 24, aged seventy nine years

Sir William M'Cormick, G B E, F R S, chairman of the University Grants Committee and of the Advisory Council on Scientific and Industrial Research, on Mar 22, aged seventy years

Prof Wilfred Robinson, professor of botany at the University College of Wales, Aberystwyth, on Mar 7

News and Views

CONGRATULATIONS from a wide circle of friends will be extended to Prof George Forbes, one of our veteran electrical engineers, who celebrates his eighty first birthday on April 5, having been born in 1849 He is the son of Principal David James Forbes, and graduating in the first instance at the University of St Andrews, he went on later to Cambridge Respecting his youthful adventures, our readers will doubtless recall a recent article in the *Times* by him recounting work as a war correspondent, and impressions, whilst in the service of Delane, the editor of that journal Forsaking journalism, Forbes embraced a scientific career, becoming in the first instance professor of natural philosophy at Anderson's College, Glasgow, afterwards devoting himself to notable electrical projects He was electrical engineer for the initial series of installations at Niagara Falls, 1891-95, besides being associated with numerous other undertakings which attest the foresight and skill of the electrical engineers of a pioneer period In 1887, Prof Forbes was elected into the fellowship of the Royal Society. He is a Chevalier of the Legion of Honour of France and honorary LL D of St Andrews

CELEBRATIONS in connexion with the eightieth birthday of Dr William Henry Welch will take place in Washington, U S A, on April 8 A broadcast of the ceremonies will be relayed from the London Regional Station at 5 P M. Dr Welch's name is a household word to doctors all over the world In 1884, when the bequest of a rich American, Johns Hopkins, led to the foundation of a new university in Baltimore, Dr Welch was chosen first professor of pathology A few years later he was joined by the late Sir William Osler as professor of medicine Mainly through the genius and enthusiasm of Welch, Osler, and the late Prof Halsted—the famous surgeon—the new school rapidly rose to the first rank, and for more than a generation Johns Hopkins has been the goal of advanced students and research workers from all parts of the world Dr Welch, who has since been Director of the School of Hygiene of the Johns Hopkins University, and is at present professor of medical history there, has lived to see the educational ideals for which he fought universally adopted, and to be admitted into the class of the great masters of medicine, the class of Lister, Koch, Pasteur, and Manson In connexion with these ceremonies in America, an address, with lantern illustrations, will be given at the London School of Hygiene and Tropical Medicine, at Keppel Street (Gower Street), W C, by the director, Sir Andrew Balfour, on Dr Welch's life and work, on the same day at 4 P M

As has already been announced, the Council of the Physical Society has awarded the Duddell Medal for 1929 to Prof A A Michelson, of the University of Chicago, and at the annual general meeting on Mar 28

the medal was handed to Mr David Mc K Key, Third Secretary of the Embassy of the United States of America, on behalf of Prof Michelson The interferometers invented by Prof Michelson, of which the first was used for carrying out in 1887 the famous Michelson and Morley experiment, have been applied by him, always with complete adequacy of design, to other important and difficult problems, most of them of audacious novelty These problems included the measurement in 1892 and 1893 of the metre in wave lengths of light, the measurement of the diameters of stars, the re measurement of the earth tides, and the testing of the effect of the earth's rotation on the velocity of light These measurements have had far reaching consequences for physical science

The difficulties of reconciling the result of the Michelson Morley experiment with the then prevailing physical conception of the nature of the universe were the direct cause of the inquiry of Albert Einstein, which resulted in the theory of relativity The measurement of the metre in wave lengths of light resulted in establishing a standard of length free from the uncertainty concerning possible variation which attaches to all material standards The interferometer for the measurement of the diameter of stars, suggested by Michelson in 1890 and first applied by him to Betelgeuse, has not only confirmed the correctness of the almost incredible dimensions yielded by indirect means of calculation, but also has detected fresh stellar phenomena in the variable diameter of Mira Ceti, and the separation of double stars too close for resolution by the unassisted telescope The invention by Prof Michelson of the echelon diffraction grating provided physicists with a potent tool for the investigation of the fine structure of spectral lines, knowledge concerning which has become of such great importance in modern physics Prof Michelson has also designed a ruling engine with which very large gratings have been ruled As a final example of his work on scientific instruments for the advancement of knowledge, mention may be made of the completion by him in 1926, with apparatus designed by himself, of a redetermination of the velocity of light The elaborate precautions taken to secure freedom from error included means whereby the distance of eighty two miles traversed by the light was measured to a higher degree of accuracy than had ever been reached in triangulation

Two honours highly prized by chemists were conferred at the annual general meeting of the Chemical Society on Mar 27 Presenting the Longstaff Medal to Dr W H Mills, the president, Prof J F Thorpe, said that this gold medal is awarded triennially to the fellow of the Society who, in the opinion of the Council, has done the most to promote chemical science by research He mentioned Dr Mills's investigations of the cyanine dyes and their uses as photographic sensitisers, and referred to his researches on the occurrence of optically active forms of those substances which possess molecular dissymmetry, such as the ketodilactone of benzophenone 2 4 2′ 4′ tetracarboxylic acid and the pyridylhydrazone of *cyclo*hexylene dithiocarbonate Dr Mills has thereby established the fact that the cause of the absence of optical activity among aromatic derivatives due to the uniplanar character of the benzenoid structure is no longer effective when two rings are joined in such a manner as to make them lie in different planes, and he has emphasised this conclusion by resolving benzene sulphonyl 8 nitro 1 naphthylglycine, thus showing that the inhibition of free rotation about a single bond leads to molecular dissymmetry The Harrison Memorial Plaque and Prize was awarded to Dr R P Linstead for meritorious original contributions to chemical science Prof Thorpe said that it is seldom that a research worker within the age limits demanded by the trust deed strikes out a line for himself and does not merely elaborate and extend the research problems on which he has been trained Dr Linstead has devised and established on a sure basis a means by which it is now possible to determine the relative proportions of the constituents present in equilibrium mixtures formed by the interchange of the $\alpha\beta$ and $\beta\gamma$ structures of substances exhibiting three carbon tautomerism, whereby the close and quantitative study of this fundamental phenomenon can be effected

The discussion on beam radio telephony in the House of Commons on Mar 27 was naturally more political than scientific Points were scored by the various speakers, but we do not think that these much affect the main issue We referred to the subject in a note in our issue of Mar 8, p 386 World intercommunication cannot be considered with regard to the interests of one centre alone When H W Nicholls read a paper on trans oceanic radio telephony to the Institution of Electrical Engineers in London on Feb 22, 1923, he described some of the results obtained by the American Telephone and Telegraph Company and the Radio Corporation, which now allow us to engineer the Atlantic radio link In particular, he described a method of suppressing one of the side bands, a discussion on the existence of which has recently taken place in our pages When we first heard perfect speech being reproduced across the Atlantic, we recognised what a debt we owed to the Americans Now Sir E Hilton Young says that if the Post Office does not co operate with Imperial and International Communications, Ltd, it must co operate with some one else In particular, he stated that it is co operating with the great American cable companies and not with British interests We think that he takes too narrow a view The Post Office is not jealous of the Imperial and International Communications, Ltd, and on many occasions it has proved that it is not autocratic It is true that the Standard Company has some American capital, but there are many other large engineering firms in Great Britain which have also American support It is a British factory employing British workers and doing a large amount of work for foreigners We see no reason why the Post Office should not establish communication with Buenos Aires through foreign capitals if it is commercially convenient The development of radio communication has been so rapid of recent years that it is inadvisable to hamper the Post Office in any way

Dr John Radcliffe, the outspoken physician who told Queen Anne that she was only suffering from the "vapours", and William III that "he wouldn't have William's two legs for his three Kingdoms", was a liberal benefactor to his own College and to the University of Oxford About sixty years after his death, the trustees under his will built the Observatory which bears his name This was done at the request of the University, and there is no doubt that the trustees from the beginning always considered that they were under special obligations to the University and City of Oxford The Observatory having lately come into the possession of £100,000 by the sale of its site, the trustees have before them a proposal to move the Observatory and its belongings to South Africa, on the ground that so large a sum could not be usefully spent on astronomy in Oxford The trust is not a department of the University but, as has been pointed out by Lord Birkenhead as High Steward, it is at least doubtful whether the trustees are so far independent as to be legally entitled to alienate from the University property with which it has been intimately connected for many years It may be noted that both the Board of Faculty of Natural Science and the Hebdomadal Council have expressed disapproval of the plan now before the trustees

Prof G von Hevesy, who delivered the Hugo Muller lecture before the Chemical Society on Mar 26, chose as his subject the chemistry and geochemistry of the titanium group of elements Speaking in English, without the aid of a manuscript, Prof von Hevesy first discussed the distribution and geochemical relationships of this group of elements, of one of which, hafnium, he is the discoverer When the earth cooled, members of the titanium group became concentrated in the earth's crust, the average titanium content of the material of the whole earth is about 1 in 600 From considerations of loss of heat by the earth, thorium has been considered to be strongly concentrated in the earth's crust, and it is significant that geochemical considerations lead to the same result Of this group, only titanium, zirconium, and thorium are found as the major constituents of minerals Discussing the comparison of the chemical properties of the elements, Prof von Hevesy mentioned that, failing an accurate comparison of ionisation potentials, the relative ionic sizes are of value There is little or no difference in molecular volume between the dioxides of zirconium and hafnium, whilst the atomic volume of hafnium is in fact slightly less than that of zirconium, the ionic radii of the two elements are equal Separation of zirconium and hafnium is rendered difficult by the very small differences in the solubilities of corresponding compounds, although advantage may be taken of such differences in double fluorides, and of the differing solubilities of the phosphates or oxychlorides in hydrochloric acid Prof von Hevesy next discussed the position of hafnium in the periodic classification of the elements with reference to its basicity, and then referred to the analytical chemistry of the group Success has attended the application of methods employing radioactive indicators to minerals containing very small quantities of hafnium, and X ray spectroscopy has also proved a valuable analytical instrument

For his Friday evening discourse delivered at the Royal Institution on Mar 28, Sir Ernest Rutherford took as his subject "The Transmutation of Matter" The idea that one metal could be transmuted into another first arose among the Greeks in Alexandria in the first few centuries A D, and spread through Europe in the Middle Ages With the discovery of the periodic relationship in the properties of the elements the belief in transmutation revived, and Faraday remarked, 'To decompose the metals, to reform them and to realise the once absurd notion of transmutation—these are the problems given to the chemist for solution" In 1919, Rutherford showed that some of the nuclei of the atoms of nitrogen could be transformed by bombardment with the swift α particles emitted by radium Afterwards, Rutherford and Chadwick found that a number of the lighter elements showed a similar effect and in all cases a swift proton was found to be emitted in consequence of a violent collision between an α particle and the atomic nucleus Our evidence indicates that in the case of nitrogen, the α particle is captured during this process and the mass of the resulting atom is greater than before In general, only about one α particle in 100,000 comes close enough to a nucleus to effect its disruption Transformation of an atom would occur also if an electron could be forced into a nucleus In recent years numerous experiments have been made to change mercury into gold and lead into mercury by means of intense electrical discharges, but there is no certain evidence that any transmutation occurs by this method Apart from the radioactive bodies, it now seems clear that a large amount of energy must be applied to produce a disruption of the nuclei of the ordinary elements The old idea that a new source of energy could be tapped by transformation of the ordinary elements now seems untenable There remains, however, one interesting possibility If hydrogen nuclei—protons could be made to combine to form a nucleus of helium, an enormous amount of energy should be emitted during this process Unfortunately, there is as yet no evidence that such a combination could be produced under conditions available in our laboratories

In the past few years there has been an unprecedented activity in the development of apparatus for all aspects of kinematography, and the number of applications for patents has been particularly large There has been much discussion as to the validity of many of these apparently new inventions These facts give an interest, over and above the purely historical, to the Will Day historical collection of kinematography and moving picture equipment, which is about to be offered for sale This collection is unique and exceptionally comprehensive There is no important stage in the development of moving pictures, with the exception of sound kinematography, which is not represented in Mr Day's collection The majority of the items are well known to the public, as they have been on exhibition at the Science Museum, South

Kensington, for a number of years At the Museum they have been so adequately displayed and tended that it is to be regretted that it appears probable that the Museum will be deprived of every item of the collection after the sale It is, perhaps, unfortunate, that the collection is to be sold as a whole We should naturally like to know that the objects representing the pioneer work of W Friese Green, R W Paul, Birt Acres, and other Englishmen had a chance of remaining in England France would doubtless welcome an opportunity to acquire the apparatus of the brothers Lumière, without having to purchase the entire collection

The Will Day collection comprises some five hundred items, including not only apparatus for recording and reproducing apparent motion, but many unique specimens of early films, and a collection of books, papers, prints, playbills, and early documents relating to the subject of moving pictures and their public presentation The illustrated catalogue of the collection, sold at five shillings by the auctioneers, Messrs Harris and Gillow, 80 82 Wardour Street, W 1, is one of the most valuable contributions to the history of kinematography yet published A detailed description of each of the separate items is preceded by a foreword on the historical development of moving pictures by Mr Will Day Tenders for the collection in its entirety have to be made to the auctioneers before noon on May 3 It is difficult to see how it will be possible to assess the value of such a collection Is it too much to hope that it will fall into the hands of a public spirited purchaser, who will see to it that each country eventually has the opportunity of acquiring that portion in which it has a national interest ?

The introduction of foreign species of animals to any country is always a matter of difficulty and generally of controversy, owing to the clashing of interests which take very different points of view The sportsman and the animal exploiter seldom see eye to eye with the purist who would reserve a country for the country's own produce The position of the sportsman is easily appreciated He is in sympathy with the preservation of the native fauna—he has indeed done much to keep it in being—but if the supply of game is to be maintained or increased where sport becomes more popular and more democratic, then he must turn to foreign birds Then he must choose amongst the species which will thrive in his own country, and from these must select those which, while affording good sport, respond most profitably to the known methods of game propagation The position is particularly interesting at the moment in the United States of America The love of sport, or at any rate the desire to shoot something within the law, is increasing there enormously, and with it the demand that there should be plenty of sporting gun fodder Where native birds are big enough and abundant enough, the only danger is that they may not be able to last out the succession of annual pushes, but where native species are not sufficient, then recourse must be made to introductions of foreign blood

The situation in the United States is put quite clearly by W L. McAtee, the biologist in charge of food habits research in the Biological Survey of the U S Department of Agriculture "Let the native game birds enjoy the protection of game sanctuaries as numerous and extensive as can be afforded, but on those parts of our domain where public shooting is practical and its continuance is desired, the practical necessities of the situation require the use of species of game birds that will produce the best results, regardless of their origin" As a consequence an inquiry has been made as to the "Game Birds suitable for naturalising in the United States," and a pamphlet under that title has been issued by the U S Department of Agriculture (Circular No 96) The dangers of introducing possible pests or foreign bird diseases, or of depleting the food supply of native birds, have been foreseen, and in selecting suitable areas for introductions consideration has been given to latitude, temperature, and precipitation compared with those of the original habitat The bulk of the species regarded as the most promising importations are various kinds of pheasants and partridges, but guinea fowls Mexican quails, bustards, and sand grouse are also recommended The natural vegetation of the United States is regarded as unfavourable to the sustenance of red grouse or black grouse, and capercailhe, snow cock, and wood pigeons are looked upon as undesirable, in the last case on account of the damage they are likely to do and in the former because of the unpalatable quality of their flesh

By the courtesy of the Trustees of the British Museum, the British Association is enabled to supplement its recent researches on ancient sites in Southern Rhodesia by a loan exhibition of all the more important antiquities from Zimbabwe and elsewhere, which were scattered among the museums of South Africa Especial thanks are due to the South African Museum at Cape Town, the Rhodesian Museum at Bulawayo, and the Queen Victoria Memorial at Salisbury, for allowing their treasures to travel so far, and also to the Government of Southern Rhodesia for permitting the exhibition of the finds from Miss Gertrude Caton Thompson's excavations last year at Zimbabwe, and Mr A L Armstrong's exploration of the Bambata Cave in the Matoppo Hills It is believed that other objects from earlier explorations at Zimbabwe are in private collections in Great Britain, and it is hoped that if their possessors are willing to allow any of these to be exhibited, they will send them without delay addressed to the Zimbabwe Loan Exhibition, care of the Director of the British Museum, W C 1 The Exhibition, which enjoys the patronage of Their Excellencies the Governor General of the Union of South Africa and the Governor of Southern Rhodesia, will be opened free to the public on Monday, April 7, in the Assyrian Basement of the British Museum, and will remain open until the middle of May

According to a message from the Riga (Latvia) correspondent of the *Morning Post*, published on Mar 24, a communist of the name Volgin has been

appointed as the new permanent secretary of the Academy of Sciences of Leningrad, after the dismissal of the former permanent secretary, Prof S Oldenburg (see NATURE, Nov 16, 1929, p 767) In an interview with representatives of the Press, the newly appointed secretary stated that a new statute of the Academy has been drafted which requires all the academicians not only to show scientific attainments, but also to pay strict obedience to political orders and to help in the Socialistic reconstruction of U S S R It appears likely that should the present policy be continued, all the older members of the Academy will soon be displaced by others, whose achievements in adhering strictly to the Soviet Government's political principles are likely to be greater than their attainments in science The recent dismissal of A A Birula from the post of Director of the Zoological Museum of the Academy is a further demonstration of the Soviet Government's attitude towards the older scientific workers in Russia During the same interview, M Volgin stated that even foreign honorary members of the Academy will be required to show themselves friendly to the revolutionary movement of the proletariat

IN the presence of members of the Council of the Research Association of British Paint, Colour and Varnish Manufacturers, Mr S K Thornley, the president, on Mar 21, laid the foundation stone of a large extension of the premises of the Research Station at Waldegrave Road, Teddington Before laying the stone, Mr Thornley said that already we have had sufficient experience of the working of the research association idea on the utilisation of existing knowledge and the discovery of new knowledge to know that it is well worth while It damages no one and is to the advantage of all Co operative research is a valuable if not the only convenient means for most people to participate in the inevitable scientific advance The foundation stone bears the inscription "Scientia socia industriae" (science the ally of industry) This stone was laid by Samuel Kerr Thornley, President, Research Association of British Paint, Colour, and Varnish Manufacturers, 21st March 1930

DR L COCKAYNE, who was awarded the Darwin Medal for 1928 by the Royal Society for his contributions to ecological botany, has been appointed honorary botanist to the Wellington City Council, New Zealand

A CONSIDERABLE earthquake was recorded at Kew Observatory on Mar 26 The first impulse reached the Observatory at 7 hr 32 min, 12 sec The records indicate that the epicentre was situated in the south west of China

AT the annual general meeting of the Television Society the following were elected officers for the current year *President*, Sir Ambrose Fleming, *Hon Treasurer*, Mr W C Keay, *Hon Secretaries*, Mr J J Denton and Mr W G W Mitchell Mr J L Baird was elected an honorary fellow of the Society

DR A T DOODSON, associate director of the Liverpool Observatory and Tidal Institute, has been awarded a prize of £150 offered by the Royal Society of Arts in 1929, under the Thomas Gray Memorial Trust, for an improvement in the science or practice of navigation, for his work on the analysis and prediction of tidal currents

AT the annual election of office bearers of the Royal Philosophical Society of Glasgow, to fill vacancies, the following were elected *Vice President*, Mr David Begg, *Members of Council*, Mr G D Buchanan, Dr G H Edington, Mr W Gillies, Prof G W O Howe, *Hon Secretary*, Prof C R Gibson, *Hon Treasurer*, Sir John Mann, *Hon Librarian*, Dr J Knight, *Hon Auditors*, Mr J T Tulloch, Mr J J D Hourston, *Acting Secretary*, Dr J M Macaulay

IT would appear that in our review of "The World's Grasses" by Prof J W Bews in our issue of Jan 25, p 119, we failed to view the entire field We are now informed by Mr A S Hitchcock, of the U S Department of Agriculture, that *Bromus secalinus* is cultivated in the valley of the Columbia River *Bromus arvensis* is also cultivated as a crop in some European countries, so that this fact should have been referred to as an addition to, rather than as a correction of, Prof Bews's statement

AT the annual meeting of the Ray Society, held on Mar 21, Prof W C M'Intosh was re elected president, Sir Sidney F Harmer treasurer, and Dr W T Calman, secretary Sir David Prain was elected a vice president and Canon Bullock Webster and Mr C H Oakden new members of the Council The Council's report announced that the issue for 1930 would consist of a volume on "The Aquatic (Naiad) stages of British Dragonflies", by Mr W J Lucas, it will be illustrated with coloured plates which are now in course of reproduction from the author's own drawings A work on "British Freshwater Copepoda", by Dr R Gurney, has been accepted for publication and its preparation is well advanced

A GENERAL discussion on "Optical Rotatory Power" will be held by the Faraday Society on Friday and Saturday, April 25 and 26, in the rooms of the Chemical Society, Burlington House, Piccadilly, London The meeting will open with an introductory paper by Prof T M Lowry, and the proceedings will be in four groups dealing respectively with (1) The physical basis of optical rotatory power, (2) apparatus and methods, (3) rotatory power of solutions, and (4) chemical aspects of optical rotatory power The programme is noteworthy for the number of foreign scientific workers who have furnished papers Members of allied societies, research students, and others interested, whether members of the Faraday Society or not, are invited to be present at the meeting

Two Chadwick Public Lectures, delivered by Mr Arthur J Martin, on "Sewage and Sewage Disposal", have been published (Macdonald and Evans, 8 John Street, W C 1 Price 2s 6d net) The booklet gives an interesting and instructive survey of the advances that have been made in recent years in the treatment of sewage, and concludes with a description of the activated sludge process, various modifications of which are now regarded as being the best means for the treatment of sewage

THE latest catalogue (No 523) of Francis Edwards, Ltd, 83 High Street, Marylebone, deals with second-hand works, 371 in number, relating to West Africa

MR J H KNOWLES, 92 Solon Road, S W 2, has just circulated a catalogue (No 11) of upwards of five hundred second hand books on botany, herbals, phanerogams, floras and cryptogams, zoology and geology

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A principal of the Castleford, Normanton, and District Mining and Technical Institute, Whitwood—M G Swaine, Education Offices, Castleford, Yorks (April 7) A head of the Department of Commerce of the Leicester College of Technology—The Registrar, College of Technology, Leicester (April 7) A junior assistant in the Wood Chemistry section of the Forest Products Research Laboratory, Princes Risborough, Bucks—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (April 8) A designing draughtsman in the Naval Ordnance Department of the Admiralty—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (April 12) A lecturer in pharmacy at the Witwatersrand Technical Institute—Chalmers and Guthrie, Ltd, 9 Idol Lane, E C 3 (April 12) A permanent assistant to the adviser in agricultural economics in the Department of Agriculture and Horticulture of the University of Bristol—The Secretary, University, Bristol (April 12) A public analyst for the Metropolitan Borough of Camberwell—The Town Clerk, Town Hall, Camberwell, S E 5 (April 14) A pathologist at the Preston and County of Lancaster Royal Infirmary —The Superintendent and Secretary, Royal Infirmary, Preston (April 17) A research worker at the National Institute for Research in Dairying, for the investigation of problems concerning accessory food factors—The Secretary, National Institute for Research in Dairying, Shinfield, near Reading (April 19) Civilian education officers in the Royal Air Force Educational Service—The Secretary, Air Ministry, Gwydyr House, Whitehall, S W 1 (April 22) A professorship of education in the University College of Hull—The Secretary, University College, Hull (April 23) A lecturer in historical geography at King's College, London—The Secretary, King's College, Strand, W C 2 (April 25) A professor of bacteriology at University College Hospital Medical School—The Academic Registrar, University of London, South Kensington, S W 7 (May 15) Probationers in the Indian Forest Service—The Secretary, Services and General Department, India Office, S W 1 (July 1) A sanitary inspector in the Sudan Medical Service—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W 1 A physics lecturer at the Newfoundland Memorial College—S T Harrington, Woodfield, Malvern Wells A lecturer in mathematics and physics in the Dudley Training College for Teachers—The Secretary to the Dudley College Council, Education Offices, Dudley A full time teacher of building and civil engineering in the Barnsley Mining and Technical College—The Principal, Harvey Institute, Barnsley

Our Astronomical Column

The New Comet Wilk 1930 *c*.—Mr J P Moller has computed the following orbit of this comet

The comet is visible both in the evening and the morning, but the morning is rather more favourable It attained the fourth magnitude at the end of March, and was visible in twilight The orbit bears some resemblance to that of De Vico's comet, 1846 iv, which has been sought for ten years, but the differences are greater than perturbations are likely to have caused It should, however, be observed as long as possible, to test for any deviation from parabolic motion

Distribution of Matter in Interstellar Space.—Dr J. S Plaskett and Mr J A. Pearce contribute an important paper on this subject to *Mon Not Roy Ast Soc* for January Some months ago Dr O Struve suggested that the intensity of the *H* and *K* lines of calcium in the spectra of early-type stars might be used as a measure of the distance of these stars, since the lines had been shown to arise from matter external to the stars The chief uncertainty was as to whether it was safe to assume that the density of the interstellar gas was uniform throughout space The present paper gives a definite affirmative answer to this question The spectrograms of 261 stars taken at the Victoria Observatory were examined, and the radial velocities both of the stars themselves and of the interstellar gas were analysed by the formulæ derived by Dr Oort for radial motion arising from galactic rotation It is found that the interstellar lines indicate a rotational term of 7 9 km/sec, indicating a mean distance of 465 parsecs, and give galactic longitude 332° (referred to the intersection of the galaxy with the equator of 1900), a value agreeing closely with that found in other ways The distances of the stars, found in a similar manner, are in the mean twice those of the gas, thus giving strong confirmation of the uniformity with which the interstellar matter is distributed, and showing that it shares in the galactic rotation

The Trans-Neptunian Planet.—The telegram announcing Dr G Struve's observation of the new planet, to which reference was made in NATURE of Mar 29, p 507, was received at the Royal Observatory, Greenwich, by telephone; through an error, the word 'planet' was taken down as 'comet' The writer of the note in NATURE learnt of the mistake and immediately communicated with the Editor, requesting the deletion of the words "who called the body a comet" Instructions were telegraphed to the printers, but the message was misunderstood, and the words appeared. Apologies are due to Dr Struve for the misrepresentation

Research Items

Indian Chronology—In the *Indian Antiquary* for February Mr F J Richards outlines a scheme of periods in Indian history which was originally put forward and discussed at a meeting of the Indian Section of the Royal Anthropological Institute The object of the scheme is to correlate the periods of the historian with the ebb and flow of culture both inside and outside India. The historic period is divided into three 'major' divisions (1) The Early, 600 B C to A D 300, (2) the Medieval, A D 300 to A D 1500, and (3) Modern, A D 1500 to A D 1900 Each of these is again subdivided into three For the early period the suggested division is (I) 600 B C to 300 B C, (II) 300 B C to 1 B C, and (III) 1 B C to A D 300 Of these, I, 600 B C to 300 B C, roughly answers to the Hellenic period of Europe, the Achæmenid period of Persia and the close of the Chou dynasty of China In northern India it covers the rise of Jainism and Buddhism and the consolidation in the lower Gangetic plain of the kingdom of Magadha Foreign influence is represented by the Persian conquest of the north west in 512 B C and the invasion of Alexander From 300 B C to A D 300, roughly the period of Hellenistic Greece and imperial Rome, covers in India the Mauryan empire at its zenith under Asoka and its partition between Sungas, Andhras and Greeks from Bactria, and at a later stage Sakas and Pahlavas from Iran, and secondly the rise and decline of the Kushan empire Southern India is obscure, but Roman traders were busy in Malabar As regards foreign contacts, the Mauryas were in touch with Greece, and the Kushans with Rome, but the main thrust came from China In the period A D 300 to A D 650 when in Europe imperial headquarters were transferred to Constantinople, in northern India the 'Gupta period' falls into two phases with the Huna invasion (480 to 528) The period 650 to 1200 covers the struggle between the Byzantine Empire and Islam, and the second great expansion of China under the T'ang dynasty and the struggle with the Tartars In India it answers to the Rajput period, a period of conflicting States around Kanauj The period from 1200 to 1500, the closing epoch of the Roman empire and of Mongol domination in Asia, witnesses two phases in the Delhi sultanate, but in southern India interest centres in the Chalukyas of the western Deccan

Mammals formerly eaten in the Dominican Republic—The examination by Gerrit S Miller of the remains of mammals from the food refuse of Indians, Spaniards, and an extinct owl left in the coast region of the Dominican Republic, has afforded interesting evidence of the presence of species now extinct, as well as of the peculiar tastes of the feeders Nineteen species are represented, and although none is new to science, new light has been thrown upon the characters and distribution of some The presence of a ground sloth is demonstrated in this recently extinct fauna, and there have been identified four of the native mammals, the hutia, the quemi, the mohuy, and the cori, which Oviedo y Valdés, the first European chronicler of West Indian history, stated about 1546, were habitually eaten by natives and Spaniards during the early years of the sixteenth century (*Smithsonian Misc Coll*, vol. 82, No. 5, 1929).

Polydactyly in Fowls.—The extra toe in fowls was first shown by Bateson to behave as an irregular dominant in inheritance, following the rule regularly in some families but being transmitted sometimes through normals without an extra toe The extra toe is also known to vary in size and in its freedom from the next Bond has shown that in cases of asymmetry it occurs more frequently on the left than the right foot Punnett and Pease (*Jour of Genetics*, vol 21, No 3) have summarised the evidence on this subject and added some fresh data which are in accord with earlier results They conclude that there is probably a definite factor for polydactyly, and that normals may transmit polydactyly owing to the presence of one or more factors which inhibit its expression In some families, the F_1 are all polydactylous, the F_2 giving 3 1, and the back-cross a 1 1 ratio This was especially true of the light dorking crosses Moreover, out of 142 polydactylous chicks, only 7 showed any degree of asymmetry The silky crosses gave more exceptions It is suggested that certain 4 toed birds may really represent double asymmetry, factors being present which suppress both the right and left extra toe Normal birds from a polydactylous parent sometimes in crosses with polydactyls give a high number of birds without an extra toe Such normals are spoken of as 'resistant', and the evidence indicates that this condition is mainly due to the presence of one inhibitor In certain cases, however, another factor must also be concerned in inhibiting the appearance of the extra toe There is no evidence of linkage between polydactyly or asymmetry and sex

Polyzoa—The presidential address to the Linnean Society delivered by Sir Sidney Harmer on May 24, 1929, on Polyzoa, has recently been issued (*Proc Linn Soc*, Session 141, 1930) In the first four sections all zoologists will find much of interest since they deal with the group in general, its economic importance, and early chapters of its history finishing with those connected with the names of Linné and Ellis The latter had remarkably clear ideas on the Polyzoa for the time in which he worked In recent years, a great deal of important work has been done on these animals by Jullien, Levinsen, Borg, and the author himself, the greater part of which has not yet found its way into the ordinary text books and so is familiar only to those who have worked in the same field These investigations have added greatly to our knowledge of the morphology and physiology of the group, and consequently modified its classification extensively Sir Sidney Harmer has reviewed this work in a critical manner and provided a clearly illustrated account of its most important results In the concluding pages is a discussion of the most recent classification that has been put forward by Borg The whole forms an interesting and useful essay for which the author deserves the thanks of his colleagues

Fresh-Water Crustacea of Norfolk—Dr Robert Gurney (*Trans Norfolk and Norwich Nat Hist Soc.*, vol 12, part 5, December 1929) gives a general survey of the fresh water Crustacea of Norfolk. He considers the plankton of the Norfolk Broads belongs generically to the Baltic type, but it has marked specific differences attributable partly to marine influence and partly to the factors of depth, size, and climate The shallow weed grown Broads are extraordinarily rich in Entomostraca but the richness depends to a large extent on the nature of the vegetation and the salinity of the water In general, the crustacean fauna is characterised by its great variety and the absence of all northern forms Of the river crustaceans the most interesting is *Leander longirostris*, the 'white prawn' or 'jack shrimp', recorded for the first time as a British species in 1921, and now known to occur

also in the Tamar in Devonshire This prawn is almost as much at home in fresh water as in salt water, its range of tolerance being much greater than that of *Palæmonetes varians*, which is very sensitive to water of low salinity The jack shrimp, however, goes to the sea to hatch its young, and indeed its eggs will not hatch in fresh water, while the larvæ of *Palæmonetes* thrive in brackish water The author does not accept the view that *Cordylophora lacustris* and *Dreissensia polymorpha* are two species actually in process of migration from the sea to fresh water *Dreissensia* is very definitely a fresh water species quite intolerant of salt water and there is no evidence that it has changed its habits in historic times *Cordylophora* is not an estuarine or even a brackish water form, and its distribution does not indicate recent penetration from the sea

Fauna of Sinai —The results of an expedition to the Sinai Peninsula in 1927, under the auspices of the Hebrew University of Jerusalem, have recently appeared as a small volume edited by Drs F S Bodenheimer and O Theodor and published by J C Hinrichs'sche Buchhandlung, Leipzig, 1929 (price 12 gold marks) The editors contribute general articles on the climate, topography, geology, etc , of the Peninsula, but the greater part of the book is devoted to the insect fauna Probably the most interesting chapters are those devoted to the manna produced on tamarisk the history of the subject, the insects responsible for the manna production, and the chemical composition of the latter being discussed There are also separate articles by specialists dealing with the Orthoptera, Coccidæ, and Formicidæ collected by the expedition With reference to the Orthoptera, it is noteworthy that the only previous account of these insects from the Peninsula is that of Krauss published in 1909 In the present collections one new genus and four new species are described, and there seems little doubt that a thorough exploration of the Sinai Orthoptera would throw considerable light upon the origin and evolution of the desert fauna generally The report, it may be added, is well illustrated by text figures and half-tone plates

Cereal Breeding —Dr E S Beaven, chairman of the Council of the Institute of Agricultural Botany, made some interesting comments upon the work of the Institute at the meeting of its Council in December 1929, which received the tenth annual report Referring particularly to the work of the Crop Improvement Branch, he pointed out that originally emphasis was laid, in the statement of the aims of the Institute, upon the growth and marketing for the trade of new varieties He points out that, as a matter of fact, in ten years the Institute " has only distributed one new variety and that was only a modified form of an older variety already in cultivation" Dr Beaven, from his long practical experience of cereal breeding, had anticipated this situation, in view of the fact that it was the Institute's declared policy " to market no new variety unless there is clear proof of its superiority to races already in cultivation in respect of probable monetary value to growers " Dr Beaven pointed out the practical significance of another task carried out by the Institute " the testing by systematic and repeated trials at our headquarters and sub-stations in six different locations—all in corn-growing areas—of the relative merits of different races of farm plants " Dr Beaven also dealt with the practical question of the return for the outlay upon work of this type carried out by the Institute. The records of the Institute's trials show that there are frequently differences of 10-20 per cent in the values of the crops due to the variety or race of seed sown Dr Beaven added · " It is a modest estimate that something over 5 per cent would be added to the monetary return of the arable farmers of the country if they all grew the races of plants best suited to their localities and soil conditions That would add about £2,000,000 every year to the net returns for arable farm produce "

Earth-Tiltings before Earthquakes —Two interesting papers have recently appeared on the tilting of the ground before earthquakes in Japan Messrs W Inouye and T Sugiyama have examined the records for nearly two years, 1927–29, of a pair of tiltometers erected at the seismological station half way up Mt Tukuba (*Proc Imp Acad* , Tokyo, vol 5, pp 457 459 , 1929) The vector diagrams show that the earth tiltings exhibit an annual variation probably connected with changes of air temperature From time to time, this regular variation is disturbed by irregular fluctuations of short period during which the earthquakes of the district usually occurred The centres of two of these earthquakes were close to Mt Tukuba Before each shock, earth tiltings were more or less pronounced for a month or more and they ended simultaneously with its occurrence Prof A Imamura and Mr T Kodaira have made similar observations on the tiltings before the Kii earthquake of July 4, 1929 (*Proc Imp Acad* , Tokyo, vol 5, pp 460-462 , 1929) The earth tiltings at Tanabe, 12½ miles from the epicentre, showed that the regular annual variation was interrupted by a ' tilt storm ' on June 20 This lasted until July 3, when the tiltings returned to normal conditions, the earthquake occurring on the following day The authors of both papers conclude that the abnormal tiltings observed were actual precursors of the earthquakes

A Grating Periodograph —An interesting application of the methods of pure science to an important industrial problem is described in the January number (vol 21) of the *Journal of the Textile Institute*, which contains a paper by G A R Foster on " The Grating Periodograph for the Analysis of Series of Observations for Hidden Periodicities " Though the procedure described is applicable to the analysis of any series of observations in which periodicities are suspected, it has been developed at the Shirley Institute, the headquarters of the British Cotton Industry Research Association, expressly for the purpose of detecting periodic variations in the dimensions and properties of cotton yarns as produced under various manufacturing conditions Briefly, the method consists of throwing an image of the graph to be tested, via a grating, on to a ground glass screen or photographic plate If the area under the curve has been previously blackened out, there are formed, at certain distances of screen and grating, bands of light and dark fringes of spacing simply related to the hidden periodicities of the curve Both the practical details and the theory of the method are given It is undoubtedly a simple and elegant way of carrying out a periodogram analysis, which furthermore allows Schuster's method of secondary analysis to be performed in a very convenient manner

Illumination Requirements —A statistical analysis of the requirements in artificial light of the average American family was recently presented before the New York section of the American Institute of Electrical Engineers The authors commenced by analysing needs in regard to ' work illumination ' (reading, writing, sewing, factory work, etc), ' social illumination ' (in the home, places of public assembly, etc), and ' utility illumination ' (passages, store

rooms, streets, etc) For these the following values of illumination (foot candles) are suggested

	Activities requiring—		
	Work Illumination	Social Illumination	Utility Illumination
A Minimum present good practice	15	5	3
B Minimum recommended	30	10	5
C Probable levels of greatest economic advantage	50	15	5
D Possible desirable levels from eye considerations only	300	50	30

An attempt is next made to determine the 'light hour' needs of the average family and hence the possible total demand for electrical energy for light in the United States The estimate based only on consideration of the eye (*D*) attains the prodigious total of 778,900 millions of units a year It appears that the total actual consumption of electricity for lighting in 1929 was about 20,000 million units It is estimated that at the levels in the above table the saturation is respectively 30, 17, 13, and 3 per cent

Conduction of Electricity in Metals —On the classical electron theory of metals, the exact hypotheses made concerning the type or absence of directed motion of the electrons were often not of great importance for the final description of any particular effect This result, which, although scarcely to be expected, was frequently useful, has now been shown by T E Stern, in a paper in the March number of the *Proceedings of the Royal Society*, to be closely connected with the fact that on classical theory the kinetic energy of the electrons is a linear function of their density On Prof Sommerfeld's theory, in which the electrons are treated as a degenerate gas, the linear dependence of energy upon density disappears, and with it the equivalence of the different methods of analysis The properties of a metal which is passing a current cannot be safely deduced from those of an insulated metal, without making careful inquiry as to the nature of the phenomenon in question, a general result which is illustrated by the special cases of the Thomson effect, the evaporation of electrons, and some others Mr Stern also raises the question of the applicability of thermodynamical reasoning, such as was applied by Kelvin to the thermoelectric circuit—a problem also recently treated by Bridgman—but shows that Sommerfeld's formula for a thermal electromotive force is in at least approximate accord with Kelvin's results Mr Stern's conclusions, although expressed in terms of the present electron theory of metals, are not entirely dependent on this, but retain their main features for any theory in which the kinetic energy is not proportional to the density

The Kennelly-Heaviside Layer —The Radio Research Board has issued a report of the work carried out from the foundation of the Board until March 1929 It is the first of a series of annual reports We learn that four committees have been appointed to study the problems connected with the propagation of radio waves, atmospherics, directional radio, and thermionic valves respectively In each of these committees radio physicists and practical engineers are adequately represented It is stated that the most important result obtained in the study of wave propagation is the direct experimental proof of the existence of the Kennelly Heaviside layer Observations under Prof E V Appleton's supervision were made at King's College, London, and at Cambridge and Peterborough with the primary object of investigating the effects of ionisation of the atmosphere on signal fading and the propagation of waves in general Considerable use was also made of a second method in which the variations of signal strength in a loop and vertical aerial are compared Transmissions on waves of 100 metres length from the National Physical Laboratory were observed simultaneously at the three stations Downcoming waves were detected at King's College, only eleven miles from the transmitter, almost as easily as they were detected at Cambridge and Peterborough This indicates reflection on this wave length at almost vertical incidence The results obtained from the three stations show very close agreement The height at which deviation of waves takes place appeared to be normally 50 70 miles, but on many occasions in the middle of the night the height was found to be 130 180 miles On such occasions the lower region is re formed after sunrise and lower heights from 50 miles to 70 miles in height are again found Day observations indicate that a third ionised region exists beneath the reflecting layers, which, however, merely attenuates the waves

Equilibria in Sulphur Dioxide Solutions —In spite of the fact that sulphur dioxide is such a well known compound, there is surprisingly little information in the literature as to the properties of its aqueous solutions In the January number of the *Canadian Journal of Research* (National Research Council of Canada), which contains several other interesting communications, there is a study by W B Campbell and O Maas of the equilibria in solutions of sulphur dioxide, which has a bearing on the sulphite cellulose industry They point out that the sulphurous acid behaves as monobasic even at high dilutions, so that SO_2, H_2SO_3, $H^{\cdot}$ and HSO_3' are the constituents concerned The proportion of H_2SO_3 decreases rapidly with rise of temperature, whilst the true ionisation constant $K = [H^{\cdot}][HSO_3']/[H_2SO_3]$ is 0 03 and does not change much with temperature Experiments on vapour pressures, densities, and conductivities of solutions of concentrations up to 8 per cent and temperatures to 110° are described which extend the results just stated These show that sulphurous acid is a strong acid, the apparently weak character being due to lack of hydration of sulphur dioxide in solution

Ignition of Carbon Monoxide —It is well known that the ignition of a mixture of carbon monoxide and oxygen is greatly promoted by the presence of small amounts of water vapour or of hydrogen In the February number of the *Journal of the Chemical Society*, Smithells, Whitaker, and Holmes describe experiments in which the efficiencies of hydrogen and water vapour are compared by passing a spark through two eudiometers in series, one containing the carbon monoxide-oxygen mixture with hydrogen and the other the mixture with water vapour in equimolecular amount When the drying of the carbon monoxide-oxygen mixture had not been greatly prolonged, it was found that hydrogen was more effective than water vapour, the estimated minimum quantities being 0 03 per cent and 0 12 per cent With more intense drying of the combustible mixture, the activity of the hydrogen was altogether inhibited In other words, the superior catalytic effectiveness of hydrogen was in its turn conditioned by the presence of a minimal quantity of water vapour It may equally well be said, alternatively, that in the presence of hydrogen a minimal quantity of water sufficed to confer ignitibility

The Pine-Sawyer Pest in Sweden.

IN No 25 of *Meddelanden från Statens Skogsförsöksanstalt*, 1929 (Reports of the Swedish Institute of Experimental Forestry), Ivar Trägårdh has a paper on the injury caused by the pine sawyer (*Monochammus sutor*, L) in Sweden and its prevention (" Om Tallbookens Skadegörelse och Bekämpande ")

It is a remarkable fact that, even in parts of Europe (it is of course more easily comprehensible in great tropical regions), so little should have been known until comparatively recently of some of the injurious forest insect pests, especially certain families and genera of beetles In his paper the author states that " some ten years ago very little was known about the pine sawyer and its economic importance in Sweden It is true that since the days of A E Holmgren it was considered a common but indifferent insect, and it was not known that the data given by Holmgren regarding the wood boring activity of *Acanthocinus aedilis* is in reality referable to the pine-sawyer "

Trägårdh published his studies on this latter longicorn in 1918, his investigations having shown that owing to the galleries penetrating deep into the wood the insect was capable of causing serious losses in timber These investigations especially led to the establishment of the fact that the ravages by this pest, after a forest fire, were very serious—" One of the most astonishing facts in the biology of the pine sawyer is its regular and extremely prolific occurrence after forest fires This is partly due to the fact that in Sweden forest fires as a rule break out at the end of June and the beginning of July just before the breeding season of the pine-sawyer But this does not explain the reason why thousands of trees a few weeks after a forest fire should be infected to such an extent that one may find as many as 100 eggs per m It seems evident that the sense of smell in the pine-sawyer is very keen and that the beetles are attracted from regions several miles away whither the reek of the forest fire is carried by the wind "

It is not certain that all authorities would agree with the author that it is the sense of smell which attracts longicorn beetles to trees in the condition they require for oviposition In the case of *Hoplocerambyx spinicornis*, the now well known serious pest of the sal (*Shorea robusta*) forests of India, Stebbing (*Ind For Insects*) attributes the power of unerringly discovering suitable trees to instinct, pointing out that a newly felled green tree will be discovered and infested within twenty four hours It is an interesting point which requires, if it is at all possible to institute them, further careful observations

Trägårdh has a number of useful observations in this paper anent longicorn groups in general, their habits of oviposition, the feeding capabilities of adult beetles and those of the larvæ, the methods of pupation and so forth The paper and the illustrations merit a careful study—for it appears undeniable that the powers of this family of beetles for destruction in the forest itself, and havoc to the timber after the trees have been felled, are equally as serious (if not more so) in sub tropical and tropical forests as is the case in European temperate ones

Geological Climates

THE meeting of the Royal Society on Mar 27 was devoted to a discussion of the subject of geological climates, which brought out several points of great interest, and showed that the conflict of views, though still considerable, is less direct than it was some years ago In opening the discussion, Dr G C Simpson defined the problem from the point of view of a meteorologist, and laid down some fundamental principles with which all reconstructions of past climates must conform He pointed out that the earth being approximately a sphere rotating on an axis inclined at an angle of about 66½° to the plane of the ecliptic, there must always have been climatic zones in which the mean annual temperature decreased from the equator to the poles, and there must always have been summer and winter

Dr Simpson then passed to the conditions existing at present, and showed that in spite of the great differences in the land and sea distribution of the two hemispheres, the mean annual temperatures of corresponding latitudes between the equator and 70° nowhere differ by more than 3° C From this he drew the conclusions that the mean temperature in any latitude is almost entirely independent of the distribution of land and water, and that the mean temperature of corresponding latitudes is always the same in both hemispheres Hence it is impossible to explain great changes of climate in geological periods by means of changes in the distribution of land and sea The reason is that the gradient of temperature from equator to poles is controlled by the strength of the atmospheric circulation, an increase of the gradient is automatically followed by a strengthening of the circulation, and more heat is carried from the equatorial to the polar regions until the balance is restored The supposition that large ice sheets could exist at sea level in the tropics, while tropical conditions prevailed in middle latitudes of the northern hemisphere, is quite untenable The only way in which major climatic changes could be brought about was by changes of solar radiation, and these had more effect on the cloudiness and precipitation than on the temperature Extensive changes of mean annual temperature could only be brought about by movements of the crust relative to the poles, in the manner described by Wegener

The subsequent discussion turned mainly on two points, the value of fossil plants and animals as indices of past climates, and the power of changes in the distribution of land and sea to modify the zones of temperature and introduce major climatic variations Prof A C Seward said that the climatic value of fossil floras has been greatly overestimated in the past, and there is now no justification for speaking of the climate of the earth as having been uniform or of high northern latitudes as having been tropical It is not possible to infer the climate from a study of extinct genera or even species, because to day allied species often live under quite different climatic conditions Moreover, in the course of ages, plants may have altered their constitution as they passed from youth to senility New plant types frequently originate in arctic regions and spread southward, while in high latitudes they are driven out by the competition of later types, but this does not necessarily imply a change of climate The vegetation of past ages was more uniform than that of to-day, but the uniformity has often been exaggerated, because the early floras consisted exclusively of gymnosperms, which resemble each other much more closely than do flowering plants There is no justification for the assumption that the vegetation of the coal-measures was tropical, on the other

hand, the presence of glaciers does not necessarily imply temperatures at freezing point, for glaciers in New Zealand still end among vegetation of sub tropical aspect

Prof J W Gregory illustrated another difficulty in the interpretation of fossil floras by showing how a coal bed may be in process of formation in Jan Mayen at present, the material being supplied by timber drifted from Siberia

Sir Peter Mitchell agreed with Prof Seward that the climatic value of fossils has been over estimated, since animals have power to adapt themselves to changing climatic conditions He added that for animal life the range of temperature is more important than the annual mean, and the annual range is closely dependent on the distribution of land and sea

These modifications of the former claims of palæontologists concerning past climates represent a great advance towards the meteorological view of the permanence of climatic zones, put forward by Dr Simpson The gap is not entirely bridged, however, for several speakers expressed the opinion that while there must always have been zones of temperature, Dr Simpson has under estimated the possible effects of changes in the distribution of land and sea Prof Gregory referred to a dictum by Lord Kelvin, that if the greater part of Europe, Asia, and North America were submerged beneath the sea, the Arctic Ocean would be free of ice, and an island at the north pole would have a mild climate Dr C E P Brooks referred to investigations by Prof Kerner and himself which led to the same conclusion, and described the transfer of heat by ocean currents, especially in the Atlantic He pointed out that the North Atlantic between 30° N and the Arctic Circle is, on the average, about 5° C warmer than the South Atlantic between 30° S and the Antarctic Circle This difference is almost entirely due to the fact that two thirds of the warm equatorial water is carried into the North Atlantic by the Gulf Stream and Antilles Current In many of the geological periods the distribution of land and sea, according to the usual palæogeographical reconstructions, was such that the whole of the warm equatorial water was diverted into the northern hemisphere, and he argued that under such conditions the oceans of the northern hemisphere must have been much warmer than those of the southern hemisphere, and the thermal equator must have been well to the north of the geographical equator Finally, Dr C Tate Regan described the distribution of fresh water and marine fishes during the Cretaceous and Eocene, which does not fit in with the drift of the continents as inferred by Wegener

The general result of the discussion may be summed up by saying that the geological changes of climate have not been so great as was at one time supposed, but there is not yet any agreement as to whether they were small enough to be accounted for by ordinary agencies, or whether they were on a sufficient scale to necessitate an appeal to movements of the continents relative to the poles

University and Educational Intelligence.

CAMBRIDGE —The Appointments Committee of the Faculty of Economics and Politics has reappointed P Sraffa, of King's College, University lecturer in economics

The Appointments Committee of the Faculty of Biology A has appointed H Gilbert Carter, of Trinity College, to be University lecturer in botany

Smith's Prizes have been awarded to R. E A C Paley, of Trinity College, and J. A Todd, of Trinity College Rayleigh Prizes have been awarded to W R Andress, of Trinity College, and L C Young, of Trinity College

LONDON —Dr Morris Ginsberg has been appointed as from Aug 1 to the Martin White chair of sociology tenable at the London School of Economics He has been University reader in sociology at the School since 1924, and has published articles and books on the science of sociology

The title of 'Professor in the University of London' has been conferred on the following members of the professorial staff of the Imperial College of Science and Technology Profs H B Baker, V H Blackman, W A Bone, W Brown, Sir Harold C H Carpenter, S Chapman, A E Conrady C G Cullis, S M Dixon, C L Fortescue, A Fowler, P Groom, J W Hinchley, H Levy, E W MacBride, J C Philip, A F C Pollard, A O Rankine, J F Thorpe, S J Truscott, Sir Gilbert Walker, W W Watts

It has been resolved to institute a University chair of physics tenable at the Imperial College—Royal College of Science

ST ANDREWS —The Senatus Academicus has resolved to confer the honorary degree of LL D on Mr James Morton, chairman and governing director of the Scottish Dyes, Ltd, and on Prof O W Richardson, Yarrow research professor of the Royal Society, at the graduation ceremonial to be held on June 27

WALES —The agreements between the University of Wales, University College, Cardiff, and the Cardiff Royal Infirmary, which establish the Welsh National School of Medicine as a separate school of the University, were ratified at a meeting of the University Court held at Cardiff on Mar 28

A MATHEMATICAL Colloquium, under the auspices of the Edinburgh Mathematical Society, will be held at the University Hall of St Andrews on July 19–30 The courses arranged include the following Rational curves and surfaces (Prof H F Baker), arithmetical properties of curves and surfaces (Mr H W Richmond), the wave mechanics (Prof C G Darwin), elementary mathematics from the higher standpoint (Prof H W Turnbull), and recent developments in symmetric functions, determinants, and algebraic equations (Dr A C Aitken), Prof E T Whittaker and others will give informal talks Particulars can be obtained from the honorary secretary of the Colloquium, Dr E T Copson, 144 North Street, St Andrews

THE University of Leeds records in its report for 1928–29 a number of important developments, marking, to quote the wording of the report, the opening of a new chapter in its history Among these are the laying of the foundation stone of a new mining block, the opening of a new wing of the textile department, the adoption of a plan for a pathological institute, the construction of a new hostel for men students, the creation of a Montague Barton chair of industrial relations, the conclusion of a reciprocal arrangement with the University of Reykjavik in Iceland for exchange of students, and the acquisition of a very valuable collection of Icelandic books The number of full time day students attending during 1928–29 was 1385, and of part-time 144, evening students numbered 223 Along with the report we have received a forty page pamphlet containing a list of publications by members of the University in 1928–29 and titles and abstracts of theses accepted for higher degrees in science (12), medicine (5), and technology (8)

Historic Natural Events.

April 7, 1408 End of Severe Winter—The winter of 1407–8 was one of the coldest of the past thousand years The great rivers of western and central Europe and the Swiss lakes were frozen for a month or more, and the ice was five or six feet thick The frost began on Nov 11 and continued until Jan 30, then, after a brief respite, it re commenced on Feb 15 and did not break until April 7 The cold was so great that the roots of the vines and fruit trees froze The water-mills were stopped, and there was a great shortage of bread as well as a lack of fuel In France the thaw of Jan 30 caused great destruction of bridges by floating blocks of ice The North Sea was said to be frozen between Denmark and Norway In Great Britain, Holinshed records that "this year the winter was exceeding sharp through frost and snow that continued and covered the ground by all the months of December, January, February, and March, insomuch that thrushes, blackbirds, and many thousand birds of the like smaller size perished with very cold and hunger"

April 7, 1420 Early Season—According to the *Journal d'un Bourgeois de Paris*, 1405–1449, at Pasques the roses were already in bloom on April 7, and were all over by May 15 At the beginning of May good cherries were on sale, and at the end of May the corn was more ripe than the preceding year's crop had been on St John's day (June 24)

April 8, 1233 Mock Suns—According to Miss Ormerod's collection, between 6 A M and 7 A M "in the parts about Hereford and Worcester there appeared four suns in the element, beside the natural sun of red colour and a great circle of crystalline colour, the which compassed with his largeness as it had been the whole circuit almost of the whole realm of England, from the sides whereof went forth certain half circles, in whose sections appeared the said four suns"

April 8, 1709 Baltic Frozen—The early months of 1709 were excessively cold in Europe, and the Baltic was still frozen and snow covered so late as April 8 The frost began between Jan 3 and 5 with a north east wind over all central and western Europe, from Stockholm and Riga to Naples and Cadiz Even the Ebro was frozen The greatest cold occurred from Jan 11–13 and Feb 24–26, but the winter was more notable for duration than for extreme severity In France the people suffered severely from hunger, and roots were eaten instead of bread In Italy the ground was deeply frozen and the olives perished, the lagoon of Venice was frozen more than a mile from shore In England the winter lasted three months, but was not exceptionally severe, and in Ireland and Scotland it was comparatively mild

April 10, 1446 Storm Flood—A terrible storm broke over western Germany, France, Holland, and Switzerland, with violent thunder, very heavy snow, and deadly cold At the same time there was a severe storm-flood in the North Sea, by which sixteen towns were submerged and about 100,000 men drowned This catastrophe was followed by a period of very cold and windy weather, especially severe from April 29 to May 10

April 10, 1657 Flood—The village of Langtoft in Yorkshire, encircled by hills, was flooded to a depth of eight feet, as shown by a memorial stone placed in one of the houses

April 11–12, 1815 Eruption of Tomboro—A volcanic eruption, one of the most violent known, began on April 5 in the island of Sumbawa (to the east of Java), culminated on April 11–12, and continued until July Out of a population of 12,000 in the province of Tomboro, only 26 survived. The sounds of the explosions were heard in Sumatra (1118 miles) and in the opposite direction at Ternate (830 miles) In Java, the darkness caused by the ashes was deeper than on the darkest night The coasts of Sumbawa and the adjoining islands were swept by a sea wave 2 12 ft. in height.

April 11, 1917 Mirage—It is recorded in the "Official History of the War, Mesopotamian Campaign", vol 3, p 316, that Gen Cayley's force had a Turkish division in front of them in a position almost destitute of cover, but they were completely hidden from view by a mirage, and fighting had to be temporarily suspended

April 12, 1527 Long Continued Rains—It rained in England every day or night from April 12 to June 3, and in May it rained 30 hours continuously, which caused great floods and much damage to the crops

April 12–15, 1920 Gale—The weather was extremely unsettled during April 1920, and at some stations the average barometric pressure for the month was the lowest on record during April An especially deep depression lay off south west Ireland on April 11–14, after which it moved north eastward, and on April 15 a wind velocity of 110 miles an hour at a height of 3000 feet was shown by a pilot balloon ascent at Lympne With high pressure over north west Africa, a violent westerly gale occurred in the Straits of Gibraltar, the wind velocity at 1 P M on April 12 being estimated as 68 miles per hour

Societies and Academies

London

Society of Public Analysts, Mar 5—S Judd Lewis (1) The spectroscopic investigation of jams An ethereal extract was examined, using a special form of sector photometer and a spectroscope 'Absorption curves' having extinction coefficients for ordinates and wave lengths for abscissæ, were disturbed by the presence of small amounts of foreign ingredients, such as benzoic acid, salicylic acid, saccharin, certain colouring matters, etc—(2) A simple polarimetric test for sugars in jams A modification of the method of determining the specific rotation of an aqueous extract of the jam, after inversion of the dissolved sugars, is described

Linnean Society, Mar 6—Sidnie M Manton Notes on the segmental excretory organs of Crustacea (5) On the maxillary glands of the Syncarida Detailed reconstructions of the maxillary glands of *Paranaspides*, *Anaspides*, and *Koonunga* have been made from fresh material obtained in Tasmania The general disposition of the coils of the efferent duct in the maxillary glands of the three types is similar, but there are differences in detail The pattern of the duct shown by *Anaspides* and *Koonunga* could have been derived from a type resembling that of *Paranaspides* in general form, but lacking its peculiar features, such as excessive duct fenestration—Major R W G Hingston In the canopy of the forest (British Guiana) An outline was given of the methods adopted by the recent Oxford University British Guiana Expedition to explore the tropical rain forest The party worked in a small area of forest on the right bank of the Essequibo River, about fifteen miles above Bartica. One of the chief objects of the expedition was to get into the canopy of the forest and to study at close quarters the life found to exist in it Hitherto our knowledge of the canopy life consisted in what could be shot from it with a gun or observed in it with binoculars from the ground Ascents were made in four places Access to the canopy was obtained either by

rope ladders or by a seat that could be hoisted on a block-and-tackle Observation posts were fixed in the canopy and rope ladders were spread in the branches, which permitted some freedom of movement in it From the collections made at different levels it is considered that a tropical forest should be regarded as consisting of strata of life spread out one above the other

Optical Society, Mar 13—T Smith Imagery around a skew ray The usual criterion by which conjugate points are defined fails unless neighbouring rays intersect in both object and image spaces The criterion is extended to include the points of nearest approach of non intersecting rays The relation connecting conjugate points is, then, of the same form as for the simpler cases generally recognised The coefficients which determine the imagery are elements of a square matrix of the fourth order A more natural matrix for refraction in three dimensions would be of the sixth order The coefficients of the eikonal and characteristic function can be derived from the elements of either type of matrix—R A Sampson The purpose and design of the new equipment at the Royal Observatory, Edinburgh (see NATURE, Mar 22, p 467)

EDINBURGH

Royal Society, Mar 17—Lt-Col L M Davies The genus *Dictyoconus* and its allies A review of the group together with a description of three new species from the Lower Eocene Beds of northern Baluchistan Numerous specimens of *Dictyoconus*, *Coskinolina* and *Lituonella* mixed indiscriminately together were found within the same narrow limestone bands The differences between these genera are shown to be confined to the peripheral portion of the test, sections reveal the closest agreement in their internal characters as a whole, their generic characters alone affording the means for distinguishing between them These Indian forms are regarded as affording clear evidence of the close affiliation of these three genera They are the first representatives of their respective genera to be found so far east, and are very similar to such western forms as *Dictyoconus egyptiensis* (Chapman), *Coskinolina liburnica* Stache, and *Lituonella roberti* Schlumberger and Douvillé—F Walker The doleritic isles of the North Minch The small islands in the Minch to the north of Skye include the Shiant and Fladda groups They are all composed of crinanite sills with 'schlieren' of syenite, essexite, and teschenite, and in some cases with floors of picrite The alkaline bands and ultrabasic floors are thought to be the result of crystallisation differentiation The sills are doubtless the continuation north of the well known Trotternish examples—**William J McCallien and Robert B Anderson** The Carboniferous sediments of Kintyre Carboniferous sediments in Kintyre form the Machrihanish coalfield, west of Cambeltown The rocks and structure of the coalfield are described and the positions of eight coal seams are indicated on a large scale map A smaller area of coal bearing strata occurs south of the coalfield in Tirfergus Glen An interesting point brought out by the study is the existence of a group of bauxitic clays and laterites at the top of the calciferous sandstone lavas. The coals of the Machrihanish coalfield are correlated with the better known members of the Ballycastle coalfield in Northern Ireland—**William J McCallien** A contribution to the geology of north-eastern Antrim, being an introduction to the correlation of the Dalradian rocks of Scotland and Ireland The following subdivisions of the Dalradian rocks of the south-west Highlands of Scotland have been recognised in north east Antrim Ben Lui schists to the north west, Loch Tay limestone and associated epidiorite, Glen Sluan schists, Green Beds, Beinn Bheula schists The Old Red Sandstone rocks from Cushendun to Cushendall are also described, and a marked resemblance is shown to exist between the Antrim rocks and those of Kintyre This paper indicates a starting point for future correlation of the Dalradian rocks of Ireland and Scotland—D F Martyn A new method of measurement of minute alternating currents The current to be measured is passed through the filament of a diode valve the main heating current in which is an alternating current of the same frequency supplied by an auxiliary oscillating circuit In these circumstances the two superposed currents in the filament settle down into a state in which they are either in the same or in opposite phase Their combined heating effect then depends simply upon the sum or difference of the current amplitudes The effect of the small superposed filament current upon the anode current is measured by a microammeter connected, with a balancing battery, as a shunt across a resistance of several hundred ohms in the anode circuit The value of the current to be measured is then found from the slope of the anode current—filament current characteristic of the valve The method is suitable for the measurement of alternating currents of the order of 1 microampere, the sensitiveness being about the same as that of the microammeter used One great advantage is that it allows each component of a complex oscillatory current (for example, a receiving aerial current) to be measured separately

PARIS

Academy of Sciences, Feb 24—Ch Fabry A new method for the experimental study of elastic pressures A description of a modification and improvement of the optical method suggested by Henry Favre—**André Blondel** Diagrams for the study of the normal running and static stability of connected alternators—Prof A E H Love was elected a *Correspondant* for the Section of Mechanics in succession to the late Sir George Greenhill—**F Marty** The distribution of the values of a meromorph function—**Guichard, Clausmann, and Billon** The influence of the initial state of certain metals and alloys on the variation of hardness as a function of cold hardening For certain alloys the curve of hardness is the same whether the initial state was cast or annealed metal This applies to copper, silver, and copper nickel alloy With copper silver alloys, on the other hand, the limit of hardness depends on the initial state—**L Ravier** The results of experiments on the thrust of soil—**Benjamin Jekhowsky** The calculation for the orientation of the great circle for seeking asteroids—**Maurice Michel** A perpetual calendar giving instantaneously the Julian or Gregorian calendar of any given year—**L Gaurier** The change of the alluvium in lakes converted into reservoirs A discussion of the problems presented by the introduction of considerable quantities of alluvium into reservoirs and the modifications in the shape of the resulting delta by lowering the water level Some actual cases are cited—**A Gruvel** The principal trawling zones of the eastern Mediterranean Fishing map of the gulf of Alexandretta—**L Décombe** The undulatory theory and black body radiation The Planck formula is deduced without recourse to the hypothesis of discontinuity for the energy—**G Foëx** The diamagnetism of the halogen ions Assuming that the diamagnetism of the neutral atoms is due to the superficial electrons, it is concluded, as a first approximation, that the diamagnetism of the ion should be 8/7

that of the neutral atom This is supported experimentally by the results of Weiss, Hocart, and Pascal. For elements other than the halogens, precise numerical data on the diamagnetism of the atom and ion are wanting —**Augustin Boutaric** and **Mlle Madeleine Roy** The radioactivity of various metals obtained from old roofs The authors confirm the results obtained by Mlle Maracineanu in that the exposed faces of old metal sheets taken from roofs are radioactive, and this applies not only to lead but also to zinc and copper roofing Discussing the various possible hypotheses as to the cause of this radio activity, the authors reject the view that the effect is due to a disintegration of the metal under the action of sunlight and consider that the absorption of radioactive emanations from the air and from rain is more probable —**H Muraour** and **G Aunis** The law of combustion of colloidal (explosive) powders —**P Bary** The study of solutions of colouring matters by pectography A plate of glass is placed vertically in a solution of the dye and this is submitted to a slow evaporation The figures formed on the glass plate are termed pectographs and fall into three groups from these, conclusions are drawn regarding the nature of the solution —**Chilowsky** A new method of gasifying heavy oils A method of preheating the air and pulverising the oil is described which, it is claimed, prevents the formation of carbon deposits and reduces the amount of tar formed below one per cent —**Mme Ramart-Lucas** and **F Salmon-Legagneur** The configuration of molecules in space The absorption in the ultra violet of the alkylmalonic acids The study of the ultra violet absorption of the acids of the malonic series leads to a different structure in space being attributed to the monoalkylacids and tho dialkylacids —**M Weizmann** and **S Malkowa** The action of the hydracids on phthalimide epihydrin—**Mme Bruzau** The preparation of some trisubstituted α-arylketones —**V Brustier** The ultra violet absorption spectrum of chelidonine From the analogy between the ultra-violet absorption produced by chelidonine and the alkaloids of the morphine group, it is considered that chelidonine is a phenanthrene derivative rather than a derivative of isoquinoline as suggested by Gadamer —**Georges Brus** and **G Peyresblanques** The fixation of ozone by unsaturated compounds Curves are given showing the velocities of absorption of ozone These give much information on the mode of formation of the perozonides and their polymers —**L Royer** The possible influence of the surrounding medium on the symmetry of the forms of some natural minerals —**Louis Glangeaud** The extension and the facies of the lower and middle Cretaceous in the Atlas coast of the north of the province of Algiers —**René Baillaud** Earthquakes and falls of roof (in mines) —**A Maublanc** and **G Malençon** The nature and the organisation of the gleba of *Battarrea Guicciardiniana* —**Paul Guérin** Hydrocyanic acid in the vetches Its distribution in the various organs of the leguminous Papilionaceæ containing a cyanogenetic glucoside In the cyanogenetic Leguminosæ, the glucoside producing the hydrocyanic acid may, according to the genus, be found localised in quite different organs Examples are given —**Maurice Hocquette**: The influence of the decalcification and of the acidity of coastal sands on vegetation —**Mlle M L Verrier** The structure of the retina of an Aga midæ *Agama Tournevillii* —**D. Santenoise, H Verdier,** and **M Vidacovitch** Pancreatic vagotonine and hepatic glycogen —**J Malassez**. The distribution of energy in the compound colours —**R Lienhart** The genetics of the castorrex rabbit This rabbit is a mutation which appeared in the Sarthe in 1919, the fur of which resembles that of the beaver —**A Lacassagne** The difference in the biological action caused in yeasts by various radiations Comparison of the action of ultra-violet rays, soft X-rays, and the α-rays on the yeast *Saccharomyces ellipsoideus* —**F Holweck** Energy study of the biological action of various radiations —**N Bezssonoff** Vitamin A and carotene —**E Couture** The oxidation of oils in the presence of irradiated sterols —**L Boëz** and **J Guillerm** The microbial factor in the manufacture of Indo-Chinese pickle (*Nuoc-mam*)

Diary of Societies

FRIDAY, April 4

Institution of Chemical Engineers (Annual Corporate Meeting) (at Hotel Victoria, Northumberland Avenue), at 11 30 A.M —Presentation of Medals The Moulton Medal, The Junior Moulton Medal, The Osborne Reynolds Medal.—At 12.15 —J A Reavell The Rôle of Science in Industry (Presidential Address).—At 2 15 —H Tongue The High Pressure Equipment of the Chemical Research Laboratory, Teddington.

Royal Society of Arts (Indian Section), at 4 30 —Lieut -Col Sir Wolseley Haig The Maratha Nation (Sir George Birdwood Memorial Lecture)

Federal Council for Chemistry (at Burlington House), at 4 30.

Society of Chemical Industry (Liverpool Section) (Annual Meeting) (at Liverpool University), at 5 —A. H Amery Methods of Extracting Oil from Seed

North East Coast Institution of Engineers and Shipbuilders (at Mining Institute, Newcastle-upon Tyne), at 6.—A. Read Ships Electrical Deck Auxiliaries

Society of Chemical Industry (Birmingham and Midland Section) (Annual Meeting) (at Chamber of Commerce Birmingham), at 6.30 —At 7 —A. R. Warnes Some Little Known Causes of Stone Decay

Society of Chemical Industry (Manchester Section) (Annual General Meeting) (at Engineers Club, Manchester), at 7 —Major A. G Church The Attitude of the Government towards Scientific Research.

Institution of Electrical Engineers (Meter and Instrument Section), at 7.—Dr E H Rayner, W G Standring, R. Davis, and G W Bowdler Studies in Low Power Factor Measurements at High Voltages.

Institution of Mechanical Engineers (Informal Meeting), at 7 —A L Stanton and others Discussion on Smoke.

Royal Photographic Society of Great Britain (Pictorial Group), at 7 —Informal Meeting

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30.—W M Hurrell Visits to Iceland and other Places
GEOLOGISTS' ASSOCIATION (at University College), at 7 30 —A L Leach Geological Structure and British Coastal Scenery (Lecture) —A. L. Leach and A C Young On a Section in River Ravensbourne Valley Gravels at Lewisham.—A. L Leach Recent Excavations in the Shooters Hill Gravel

SATURDAY, APRIL 5

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (at Town Hall, Manchester), at 10 30 A M —D T Tansley Town Planning in the Manchester Regional Area —H. C Swindells Road Construction in Manchester
GILBERT WHITE FELLOWSHIP (Annual General Meeting) (at 6 Queen Square, W C 1), at 2 30 —At 3 —Sir Richard Gregory Primitive Astronomy (Lecture)
INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (at College of Technology, Manchester), at 4 —E J L. Howard and H Milner Some Aspects of Foundry Service to Engineers
MINING INSTITUTE OF SCOTLAND (at Glasgow) —Annual Meeting

MONDAY, APRIL 7

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4 30 — Sir Edgar Jones The Empire Canning Industry
ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —General Meeting
SOCIETY OF ENGINEERS (at Geological Society), at 6 —R. Borlase Matthews Rural Electrification and Electro Farming in Great Britain
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —J H Worthington Antonio da San Gallo the Younger
ROYAL SOCIETY OF ARTS, at 8 —Comdr F G Cooper Aids to Navigation (Thomas Gray Lectures) (3)
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8 —C Ainsworth Mitchell Circumstantial Evidence from Fibres and Hairs —J P O Callaghan Recent Advances in Water softening Practice
SURVEYORS INSTITUTION, at 8 —Prof T Wibberley The Future of British Agriculture
TWICKENHAM LITERARY AND SCIENTIFIC SOCIETY (at Free Library, Twickenham), at 8 —C Carus Wilson Coal
ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8 30 —Miss E J Lindgren North Western Manchuria and the Reindeer Tungus
TEXTILE INSTITUTE (London Section) (at Clothworkers Hall, E C) — W Kershaw Scientific Research as it affects Cotton Manufacture

TUESDAY, APRIL 8.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5 30 —N Matheson Some Features of Modern Steam Operated Deep Hole Rotary Drilling Plant.
INSTITUTION OF CIVIL ENGINEERS, at 6 —B B Haskew The Rebuilding of the Bassein Bridges on the Bombay, Baroda, and Central India Railway — W T Everall The Reconstruction of the Attock Bridge across the River Indus on the North Western Railway India.
INSTITUTE OF MARINE ENGINEERS, at 6.30 —S L Archbutt Recent Metallurgical Research in Relation to Marine Engineering.
INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (Annual General Meeting) (at Royal Technical College Glasgow) at 7 30.
QUEKETT MICROSCOPICAL CLUB, at 7 30 —Dr B F Barnes Induced Variation in Fungi.
EUGENICS SOCIETY (at Linnean Society), at 8 —Dr M Hamblin Smith, Judge R E Moore, and others Discussion on Delinquency
TELEVISION SOCIETY (in Botanical Theatre, University College), at 8 — Dr T H Harrison Photo Electric Cells and their Applications
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 —A D Hornblower The Elements of Egyptian Religion
ROYAL SOCIETY OF MEDICINE (Psychiatry Section) at 8 30 — Dr E Mapother and Dr A A W Petrie Impressions of American Psychiatry
ILLUMINATING ENGINEERING SOCIETY —S. Anderson Textile Lighting

WEDNESDAY, APRIL 9

GEOLOGICAL SOCIETY OF LONDON, at 5 30. — Dr L. W Collet The Structure of the Canadian Rockies
INSTITUTION OF CIVIL ENGINEERS (Informal Meeting), at 6 — S T Dutton Recent Developments in Railway Permanent Way Practice, with Particular Reference to the Use of Metal Sleepers.
INSTITUTE OF CHEMISTRY (London and South Eastern Counties Section), at 7 —Dr R M Brontë The Medical Witness
ROYAL SOCIETY OF ARTS, at 8 —Prof F A. E Crew Genetical Methods of Live Stock Improvement.

THURSDAY, APRIL 10

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr R H Crowley Parent Education, the Home and the School
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—S W Melsom, A N Arman, and W Bibby Surge Investigations on Overhead Line and Cable Systems.
INSTITUTE OF MARINE ENGINEERS (Junior Section), at 7 —Film Display The Manufacture and Operation of the Babcock and Wilcox Water tube Boiler, etc.
INSTITUTE OF METALS (Swansea Local Section) (at St. Thomas s Café, Swansea), at 7 —Annual General Meeting
INSTITUTE OF METALS (London Local Section) (Annual General Meeting) (at 83 Pall Mall), at 7 30.—Discussion on The Solidification of Metals
ROYAL SOCIETY OF MEDICINE (Neurology Section) (at Hospital for Epilepsy and Paralysis), at 8 30 —Clinical Meeting
BRITISH INSTITUTE OF RADIOLOGY, at 8 30.
ROYAL SOCIETY OF MEDICINE (Disease in Children Section).
OPTICAL SOCIETY (at Imperial College of Science and Technology).— Annual General Meeting
INSTITUTION OF WELDING ENGINEERS.—H. B White and R Tuddenham Some Interesting Arc Welded Jobs

FRIDAY, APRIL 11.

ROYAL ASTRONOMICAL SOCIETY, at 5 —R. O Redman The Galactic Rotation Effect in Late Type Stars
PHYSICAL SOCIETY (at Imperial College of Science), at 5 —Prof P Debye The Scattering of X Rays in Gases in Relation to Molecular Structure (Guthrie Lecture)
BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting), at 5 —Discussion on Radiology in Bone Tumours.
MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6
INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6 15 —Col Sir T F Purves Address
INSTITUTION OF CHEMICAL ENGINEERS (at Municipal College of Technology, Manchester) at 7 —Dr W H. Hatfield The Fabrication of Acid resisting Steel Plant (Lecture).
OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall, Manchester), at 7 —Annual Meeting
JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —W T Dunn Gas in Japan and the Far East.
INSTITUTE OF METALS (Sheffield Local Section) (Annual General Meeting) (at Sheffield University), at 7 30 —F Russell Refractories and their Uses
SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Chemical Society) at 8 —Discussion on Asphalt as a Chemical Engineering Material —A W Attwooll The Principles of Manu facture of Mastic Asphalt —D McDonald Experience with Some Applications of Mastic Asphalt in a Chemical Works
ROYAL SOCIETY OF MEDICINE (Electro Therapeutics Section), at 8 30 — Dr H A Bulman Dr L H Clark, Dr S Russ, and Dr S Wright The Physiological Effects of Penetrating X Rays upon the Cat and Rabbit.
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at Manchester) —Dr J L Hankey Some Remarks on the Treatment of Aniline Black subsequent to Ageing

SATURDAY, APRIL 12

PHYSIOLOGICAL SOCIETY (in Department of Physiology, University, Louvain), at 10 A M —G Debois Glycogen Recovery after Mammalian Muscular Activity as an Insulin Function —C Heymans and J J Bouckaert Sinus Caroticus Reflexes upon Venous Pressure, Liver Volume, and Heart Volume —P Rylandt Conduction in Mammalian Auricles —J Morelle Calcium Shifting Experimental Rickets — J P Bouckaert, J L Petit, and J de Blende Variations in Muscular Viscosity —J P Hoet and H Ernould On the Nervous Control of Insulin Secretion —P de Nayer Glycogen Deposition in Rabbits Muscles —L de Borggraef Ions and Excitability —E J Bigwood Chemical Properties of Gelatin Jellies — Thomas The Nature of Blood Sugar —T Lewis Reaction of the Human Skin to Cold — Prof A. V Hill The Osmotic Pressure of Muscles —Dr W Cramer On Inhibition of the Adrenal Gland and Vitamin B Deficiency —Dr J F Fulton Dr E G T Liddell, and D McI Rioch The Influence of Experimental Lesions of the Spinal Cord upon the Knee jerk and Crossed Extensor Reflexes —E W H Cruickshank An Adjustable Automatic Shaker for Gas Analysis.—*Demonstrations* —F Malengreau Micromethod for Estimation of Bismuth in Biological Material — J Rutten Isoelectric Point of Bence Jones Protein —J Morelle Calcium Shifting Experimental Rickets —J P Bouckaert Deter mination of Muscular Viscosity — A. K M Noyons Differential Calorimeter

PUBLIC LECTURES

TUESDAY, APRIL 8

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, at 4 — Sir Andrew Balfour The Life and Work of Dr William Henry Welch
GRESHAM COLLEGE, at 6 —Sir George Newman Physic. (Succeeding Lectures on April 9, 10, and 11)

ANNUAL MEETING

APRIL 9, 10, AND 11

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts).

Wednesday, April 9 at 11 A M —Presentation of Institution Gold Medal to J Johnson and Premium to Lieut -Col F Dondona
Lord Wester Wemyss Presidential Address.
Sir Westcott S Abell and A. J Daniel Safety of Life at Sea (1929 Conference).
Eng Capt J Hope Harrison Some Materials used for Naval Engineering Purposes.

Thursday, April 10, at 10 30 A M —Dr W M Meijer Recent Results Obtained in Service with the High Pressure Steam Installation of the Holland America Liner *Statendam*.
W J Belsey Performance of Two Vessels with Electric Transmission Gear
At 2 30 —Col. F Modugno On the Final State of a Gas Discharged from a Reservoir into a Space under Constant Pressure
Dr B C. Laws Notes on the Behaviour of Two Passenger Vessels during a Voyage to and from Australia.
F H. Alexander Stability of a Vessel with a List.
Prof E G Coker and G P Coleman Stress Distributions in Notched Beams, and their Application

Friday, April 11, at 11 A.M —R Sulzer Causes and Prevention of Vibration in Motor Ships.
Dr J L Taylor Vibration of Ships.
Lieut. Col. F Dondona Sea Trials of Italian Flotilla Leaders.
At 3.—G S Baker and Miss E. M Keary Experiments on the Resistance and Form of Towed Barges.
W C S. Wigley Ship Wave Resistance—Some Further Comparisons of Mathematical Theory and Experiment Result

SATURDAY, APRIL 12, 1930

Experimental Work in Cotton Growing[1]

THE record of the valuable experimental work carried out under the ægis of the Empire Cotton Growing Corporation is brought down to the season 1928–1929 in the seventh volume of the series of reports The series possesses a double value It gives, as a continuous record, the progress of the experimental work in each country, from which it is possible to trace how one problem, by its solution, has led to another It also contains a record of the latest work in each country and should be of the greatest assistance to those faced with similar problems and difficulties elsewhere

The function of the stations from which reports are issued is to achieve practical results for the benefit of those growing cotton in the areas they represent To achieve those results it may be necessary to extend investigation by the inclusion of work of a more academic nature But by their practical results they will be judged It is pleasant, therefore, to note the considerable success achieved in this direction In the Jassid resistant *U4* cotton, South Africa has received a strain which can reasonably claim to have saved the situation, for, without it, cotton growing within the Union appeared to be doomed Pessimism is giving place to optimism, and, what is more, the success does not appear to be confined to the Union alone but it extends also to the two Rhodesias and Nyasaland In Fiji, too, the introduction of a Kidney cotton from New Guinea promises a definite benefit to the island in that its produce will no longer be confined to the narrow market for Sea Island cotton

The individual reports afford complete justification of these experiment stations by the indication given of appreciation of the practical results achieved In these are to be traced the influence of the particular economic conditions In South Africa it is the need for a Jassid resistant strain that has dominated the work , in Queensland it is cultural methods In the Sudan, matters are more complicated by the very diverse systems under which cotton is grown—systems which embrace the canalised area of the Gezira, the flood areas of Kassala and Tokar, all three of which are suited to Sakel, the pump irrigation systems of the Nile valley with their American strains, and the rains areas of the southern Sudan where American cotton is grown Here, perhaps, the need for meeting the pests, thrips, black arm, and now leaf curl, which

[1] Empire Cotton Growing Corporation Reports received from Experimental Stations, 1928–1929 Pp xi+268 (London) 2s 6d.

have successively attacked the crop, is predominant, and behind these lies the curious phenomenon of the suppression of fruiting branches, now interpreted as a conversion of sympodial into monopodial (vegetative) buds under the influence of abnormally high temperatures, which has given a physiological bias to the work. Despite these special demands, however, a broader attitude is being adopted towards the cotton crop, as is apparent from a perusal of the series of reports which have been issued. Increasing recognition is given to the fact that cotton cannot be treated in isolation and must be considered in its relation to other rotational crops. Rotations and fallows receive more detailed attention in the present than in earlier reports.

The reports issued by the Empire Cotton Growing Corporation give a sharp impression of the dominating influence played by insects in determining the success attendant on cotton growing, and of particular interest is the evidence from the Sudan, which indicates that leaf curl is a virus disease carried by a Jassid. So long as these conditions prevail, cultural problems must predominate. Until effective means of insect control are forthcoming, the problem takes the form of finding a plant sufficiently resistant to withstand the attacks, or of finding the conditions under which those attacks may be rendered least damaging, and any attempt to meet mill requirements and to apply recent knowledge as to the effective lint characters in producing a good spinning cotton must remain a secondary consideration. It is not surprising, therefore, that but little reference is to be found to this aspect, in which so vast a field remains to be explored.

The reports summarise a vast amount of work in many directions, and there arises a temptation to wonder whether the fullest use is being made of this mass of material. Cotton, in all its varieties, grows under a very wide range of conditions. In the majority of countries it matures on a falling temperature, and a limit to production may be imposed either by cold or by lack of humidity. But in the Sudan it matures on a rising temperature, while in Uganda, Fiji, and, to a lesser extent, in the West Indies, it is excessive humidity that predominatingly determines production. Thus the range of conditions covered by the various experiment stations is very wide.

The more fundamental problems underlying cotton growing may be approached in two ways. Detailed research in field and laboratory at a well equipped research station can do much. It is the intensive method. But the station must be localised and choice inevitably falls on that locality in which the plant is exposed to the minimum of risk, where, that is, limiting factors rarely come into play. Owing, however, to the variety of the conditions under which cotton is grown on a commercial basis, the question of limiting factors has an importance secondary only to that of pests; they may even be in large measure the cause of the severity of those diseases. With evidence that this is so the reports abound.

In these circumstances there is abundant scope for what may be called the extensive method of investigation—the comparison of different strains under the range of conditions available, so that they may be subject now to one limiting factor and now to another. Many strains are, it is true, at present so grown and must be subjected to a number of different limiting factors. But what steps are being taken to ensure that comparable records of growth are secured, together with comparable records of the various environmental conditions? And, if these steps are being taken, in what way are these records being co-ordinated and the results extracted? On these questions the reports are silent.

Folk-lore of the North American Indians

(1) *Tales of the North American Indians.* Selected and annotated by Prof. Stith Thompson. Pp. xxiii + 386. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1929.) 27*s*. net.

(2) *Prairie Smoke.* By Melvin R. Gilmore (Pahok). Pp. xiii + 208. (New York: Columbia University Press; London: Oxford University Press, 1929.) 12*s*. 6*d*. net.

A REPRESENTATIVE collection of the legends and traditional tales of the North American Indians might provide both a history and a textbook of the method of folk-lore. In no other part of the world have these stories been collected with greater assiduity and over a longer period of time, and in few, if any, do they cover a wider range of theme. Nearly three centuries have passed since the Jesuit fathers in 1633 first recorded tales current among the Indians with whom they had come into contact. To-day, the Bureau of American Ethnology, the American Museum of Natural History, the American Folklore Society, and the Anthropological Division of the Canadian Geological Survey are still engaged in the task of gathering up such remnants of this once great oral

literature as survive, with some vigour, among the remoter American peoples

In the relatively long period over which the work of collecting Indian tales has been spread, naturally there have been many changes in the attitude of the collectors towards their material and in their methods. They range from the sentimentalities of Schoolcraft and the conscious attempts at artistry of the early and middle nineteenth century to the severely scientific aim of the Bureau of Ethnology with its elaborately phoneticised text and literal and interlinear translations Somewhere, perhaps midway, between these come the contributions which educated Indians themselves have made to the record, varying a great deal in value, but often of noteworthy scientific import

During the last thirty or forty years the work of collection has proceeded apace, and on intensive lines varying to some extent, but not entirely, with the conditions of collection Thus Prof Boas has published a large number of texts received from the tribes of the north west coast and the Eskimo, the late Mr Hill Tout specialised in the legends of British Columbia, Dr Dorsey in the tales of the Plains Indians, James D Teit in those of the Thompson Indians, while F H Cushing made their mythology part of his intensive study of the Zuñi Indians These are a few only of the better known It is on the collections of these and others working on the same lines, rather than on original observation, that writers on Indian folk lore have relied when they have sought either to give a generalised view of the imaginative side of the Indian or have aimed at literary and artistic effect

(1) While Prof Stith Thompson aims at a comprehensive and representative collection of Indian legends and traditional tales, both in spirit and in method, he is strictly scientific Except for certain very slight modifications to meet the requirements of the general public, which will be obvious to everyone familiar with the Indian modes of presentation and phrasing, he has reprinted his stories in the words of the original translation, often happily preserving the style of the Indian narrator Not only are the stories representative of the various Indian tribal groupings, extending in the geographical sense from the polar north to Mexico, but also they are equally characteristic in the matter of theme Excepting in the first section of mythical stories, which follows a geographical order, the grouping of the tales is by theme Of these groups there are six—mythical incidents, trickster tales—a characteristic section which brings out the peculiar and somewhat cynical humour of these people—and hero tales, journeys to the other world, animal wives and husbands, and miscellaneous—a group which is not the least interesting It must not be thought, however, that the headings indicate the full scope of the interest of the tales to the student of folk lore *motif* An appendix of comparative notes reveals how rich American Indian folk lore is in this respect There are few of the *motifs* found in the legendary lore of other parts of the world which do not appear either incidentally or in chief in the tales of North America This appendix in itself, with its large number of references to Indian parallels, is alone a contribution to American folk lore studies of high value

Two very interesting questions are those of distribution and the closely related topic of the differentiation between the tales told in the various cultural areas into which American anthropologists divide the peoples of the continent Upon these points Prof Stith Thompson touches illuminatingly, if only briefly, in his introduction Many of the tales are common in their distribution, varying of course in their cultural background according as they are found among woodland, plains, pueblo Indians, and the rest But he goes on to show that in each group certain characteristic differentiations are to be observed Among the Eskimo, for example, the tales have a low level of interest, while the tales of the Plateau show a marked individuality, on the North Pacific coast there is a considerable variety, and, as might be expected from their totemic system, tales of animals, of whale and salmon, of ritual and social rank, are prominent, as well as tales of the other world In California the Indian seems to be interested only in the Creation and in the trickster

Two sections in addition to those already mentioned have a special interest for the student of modification in folk tales owing to contact Of these, one includes a number of tales derived from European sources, including Cinderella It may be mentioned in passing that in the south eastern States there is also evidence of negro influence The second group consists of tales drawn from Bible sources It is rather remarkable, in view of the widespread flood legend, that the story of the flood, as told here, is concerned entirely with the incident of Lot and his daughters, which is transferred to Noah

(2) "Prairie Smoke", more popular in form, may yet be taken as not unworthy of a place on the shelf with Prof Stith Thompson's more

elaborate work It deals with the Indians of the prairies, and while it consists in the main of their legends classified under sections to exhibit their modes of life and thought, it illustrates these with incidental descriptions of their culture and by references to events in their history

The Astrolabe

Early Science in Oxford Vol 5 *Chaucer and Messahalla on the Astrolabe* Now printed in full for the First Time with the Original Illustrations By R T Gunther Pp ix + 234 + 25 plates (Oxford Dr R T Gunther, Magdalen College, 1929) 42*s*

UNTIL the use of the quadrant became universal towards the latter half of the eighteenth century, the astrolabe was one of the most important scientific instruments at the disposal of astronomers and travellers It seems to have been invented in the time of the Greeks, and a number of elaborations made it in the medieval period not only an efficient observing instrument but also a portative set of astronomical tables It was of simple construction, not readily put out of order, and its graduation presented no great difficulties to skilled workmen There does not seem to be any reason, indeed, why it should not be reintroduced for making observations not requiring any high degree of accuracy

The astrolabe consists of a circular plate of metal from four inches upward in diameter In the portative forms a ring is attached for suspension from the finger A raised rim on the front makes a bed for a perforated plate called the 'net' On the back is a revolving bar with sights raised at each end The circle is graduated in degrees, days, and months concentrically, and there is in the middle a scale for measuring heights, etc On the front are concentric circles for the tropics and equinoctial line, a set of circular arcs giving altitudes, azimuth lines dividing the horizon into twenty four parts, and twelve similar arcs showing planetary hours The net lies over this, revolving freely, it marks the longitude and latitude of the principal fixed stars, and the zodiac The astrolabe was usually graduated for a particular latitude, but one form is adapted for use anywhere By it the altitude of the sun or a star, the time by day or night, the position of the moon, the height or depth of any point accessible or otherwise, and the hour of high tide, among other things, were found by simple observations

Chaucer's treatise on the astrolabe, written for the use of a child of ten, is a very satisfactory elementary text-book, provided that the pupil has the instrument in his hands, without this aid an understanding of the working requires attention Still, the disuse of astronomy as a foundation for astrology, and the alteration in our views on the solar system, have not altered the facts of the daily change in the aspect of the starry heavens, and if some simple form of the astrolabe could be brought into use in our schools, a standing blot on our educational system might be removed It is little short of lamentable that a boy may go through school and university without being able to point out any feature of the sky but the Plough and the Pole Star It is perhaps hopeless to expect any change from this in our town bred civilisation

The treatise was printed sixty years ago by Skeat for the Chaucer Society with a very full apparatus, including the text of the astronomical work which had been followed in its composition No better or fuller book on the subject has yet appeared The very handsome and well printed volume before us covers much the same ground as Skeat's edition, though with less help to the reader in the way of explanatory notes The title-page is a blot upon the book, a monumental piece of vandalism A page of a Chaucerian manuscript has been reproduced with the central portion of the text faded out to allow the insertion of the name of the work, of its editor, and of the claim that it is "now printed in full for the first time with the original illustrations"

This claim has only a modified justification The volume contains a modernised form of Chaucer's text, together with much of Skeat's text in the original spelling, some passages completing the subject from Chaucerian manuscripts (whether by Chaucer or no), and the "original illustrations" Of these, less than one-third are photographic reproductions from manuscripts of the astrolabe, the remainder are to all appearance photographed from modern copies of presumably medieval diagrams How far this justifies the editor's claim is a matter of opinion

The larger part of the volume is devoted to Messahalla, the author from whom Chaucer drew his information We are given the Latin text of his two treatises on the construction and on the use of the astrolabe together with a translation at once accurate and readable The texts were printed by Reisch in the sixteenth century and one of them by Skeat In addition to these the editor has given a facsimile of a Cambridge manuscript of the "De compositione astrolabii" There can be nothing but praise for this feature of the volume—every

important manuscript ought to be photographed at the earliest possible moment—but reproductions expose their editors to trying comparisons A single page of the MS (fo 62v) compared with the corresponding pages of expanded text reveals seven slips in copying The page was taken at random, and the slips were not important enough to affect the meaning

What is rather more important is that the editor should have neglected the opportunity of using his own powers of exposition to make the subject as clear as possible to the scientific reader At least he ought to have given us a series of photographs of an ordinary astrolabe bringing out its constituent parts, such as were published some years ago by the Indian Archæological Survey It is quite understandable that Dr Gunther should wish to include Chaucer's treatise in his collection of "Early Science in Oxford", but it then became incumbent on him to bring it home to modern readers R S

Kant's "Critique of Pure Reason".

Immanuel Kant's Critique of Pure Reason Translated by Prof Norman Kemp Smith Pp xiii + 681 (London Macmillan and Co, Ltd, 1929) 25s net

IT is astonishing how long the English speaking public has had to wait for an adequate translation of Kant's epoch making work The "Critique of Pure Reason" was published in 1781, all but a hundred and fifty years ago, and the first English translation did not see the light until 1838 The translator enlarges in his preface on the difficulty of rendering "so entirely novel and original a mode of philosophising", and almost disarms criticism by the modesty with which he acknowledges "how frequently, with every endeavour to be correct, he may have failed in a right understanding of his author" Meiklejohn, who next essayed the task, in 1855, produced a version which, in lack of a better, was destined to serve the needs of successive generations of students for three quarters of a century It is true that in 1881, the centenary of the original, a fresh translation was given to the public with an authoritative gesture by Max Müller This was certainly in point of accuracy and general effect distinctly better than Meiklejohn's, but by an unfortunate error of judgment the translation was made from Kant's first edition, whereas the second edition of 1787, in which Kant re-wrote important sections, must be regarded for ordinary purposes as the authoritative text of the work Unfortunately, too, the translation, at least as originally issued, was encumbered, by way of introduction, with a crudely written historical sketch of all previous philosophy by Prof L Noiré, extending to no less than 360 pages For its irrelevance and lack of all proper perspective, this so-called introduction was drastically characterised at the time by the late Prof Adamson as "comprehended under the well known definition of dirt matter in the wrong place" Under these disadvantages it was no wonder that the centenary translation failed to 'catch on', and Meiklejohn continued to be the ordinary student's vade mecum up to the present day This was perhaps scarcely to be regretted, for, although of course absolutely competent in his knowledge of German idiom and his mastery of the English language, Prof Max Muller was, after all, not a professional philosopher, and Adamson in his careful and appreciative review of the book for *Mind* felt "constrained to add that the ideal translation does not yet seem to have been attained" After giving examples of his meaning, he concludes in fact that the translation "stands in need of a thorough revision from the philosophical point of view"

The ideal is, I suppose, under human conditions never fully realised, but I think Prof Kemp Smith's translation must at least come very near to satisfying Adamson's exacting demands Prof Kemp Smith is in the best sense of the word a philosopher by profession, and moreover he has devoted the maturity of his powers to an exhaustive study of the Kantian philosophy and more particularly of the "Critique of Pure Reason" His "Commentary" on that work was recognised at once on its appearance, in 1918, as raising the study of Kant in Great Britain to a higher level There is room, of course, for difference of opinion in regard to certain of his conclusions, but his firm grasp of the whole subject was everywhere apparent, especially in the use he made of his extensive literature which has grown up round the "Critique" in Germany since 1880 A better preparation for the work of translation can scarcely be imagined, and students of philosophy may congratulate themselves that he has found leisure to carry through what must have been of necessity a laborious and often an irksome task For, as he truly says at the outset of his "Commentary", "the 'Critique of Pure Reason' is more obscure and difficult than even a metaphysical treatise has any right to be" In his other works Kant often writes as clearly and forcibly as anyone could wish, but

in this "Critique" there can be no doubt that many of the difficulties which embarrass a translator (and as Prof Kemp Smith says, "multiply rather than diminish upon detailed study) are due to the circumstances in which the work was originally published" Kant has told us himself how he pondered the subject for at least twelve years, whereas the book itself was hurriedly "brought to completion" within four or five months, in the fear lest, if further delayed, it might never see the light at all This was for long taken to mean that the whole work was written during these four or five months of 1780 But much light has been thrown more recently upon Kant's habits of working by the publication of "Reflexionen" and "Lose Blätter" found among his papers, and it is practically certain that Kant must have possessed similar drafts of portions of the "Critique", written at different times during the twelve years of incubation These he would naturally use to piece out his argument, without noticing possible inconsistencies in detail with the positions in which he had finally come to rest Patient criticism has indeed succeeded in establishing that the "Critique" is to that extent a composite work, different parts of which belong to different stages in the development of Kant's views

The present translation follows the text of the second edition, but gives at the foot of the page all the passages from the first edition which have been omitted or altered in the second The pagination of the two editions is also given in the margin as A and B Where emendations of the German text have been suggested by successive editors, Prof Kemp Smith gives in a footnote the reading which he follows, and wherever there might be a doubt as to the precise meaning of an English word or phrase in the translation he has similarly added in a note the German equivalent This critical apparatus is welcome, and was indeed essential in the present edition, but for the ordinary student, not conversant with German and intent only on a trustworthy translation, it is in a sense a luxury As Prof Kemp Smith's version must now rank as the definitive and authoritative English translation, it is to be hoped that the publishers may soon see their way to issue an edition of the text alone at a more popular price In such a text book it would be desirable to make the translation of the second edition read continuously and to relegate the variations of the first edition, including the two long sections re written by Kant, to an appendix

A S PRINGLE-PATTISON

Our Bookshelf.

Die Salzkäfer der Nord- und Ostseeküste mit Berücksichtigung der angrenzenden Meere sowie des Mittelmeeres, des Schwarzen und des Kaspischen Meeres, eine ökologisch biologisch-geographische Studie Von Hanns von Lengerken Pp iv + 162 (Leipzig Akademische Verlagsgesellschaft m b H, 1929) 8 75 gold marks

THIS is a very useful account of the beetles which inhabit the salt water coastal regions of the North Sea and Baltic The author divides them into three groups which he calls 'Haloxenen', 'Halophilen', and Halobionten' The first is omitted as the beetles are only brought into the salty region by outside agencies, such as winds and storms, the second includes those species which are not dependent on salt but are chiefly found in salty situations, the third are truly dependent on salt and never found elsewhere

At present, however, there seems to be nothing positive known as to the influence of salt on the beetles The only truly marine species in the region is *Macroplea mutica*, although such brackish water forms as the *Ochthebius* species may also be admitted By far the most of the salt water Coleoptera come under the heading 'Coastal beetles', and there are a large number of these belonging to 63 genera and 17 families A detailed study of distribution is given, and, for the purposes of comparison, neighbouring coasts other than the North Sea and Baltic are reviewed as well as the Mediterranean, the Black Sea, and the Caspian Sea

This ecological, biological, and geographical study is of great value and the notes on the various species are extremely interesting, for, besides morphology, habitat, and food, the life histories are included whenever possible Much of this is the author's own work, and one reads with pleasure his detailed accounts of *Cicindela hybrida marina* living on fine sand and in sandy burrows, and *Hæmonia (Macroplea) mutica* which is in all stages peculiarly adapted for breathing under water So delightful and lifelike are the pictures of *Cicindela* that one wishes there were more figures in the book One also misses a detailed index, only a table of contents going as far as the genera being given There is a good bibliography, most of which is divided geographically

The Economic Life of the Ancient World By Jules Toutain Translated by M R Dobie (The History of Civilization Series) Pp xxvii + 361 (London Kegan Paul and Co, Ltd, New York Alfred A Knopf, 1930) 16s net

THE 'Ancient World' with which M Toutain deals is that of the Mediterranean area, or rather of Greece and Rome with other countries considered only as subsidiary to these He begins his story with the Greece of Homer and Hesiod and traces its economic development down to the end of the Hellenistic period He then turns to Rome and the western Mediterranean, but before dealing with Italy and Rome's historic rival Carthage, to pro-

vide a background for the picture, he analyses the economic activities of prehistoric man Thence the economic system of Rome is traced until it reaches its culmination under the Antonines and finally breaks up before the inroads of the barbarians

M Toutain's subject is one of some difficulty, for outside certain aspects which were the problems of ancient society, such as the agrarian question at Rome, direct evidence is scanty The author shows little inclination towards generalisation and theory He prefers matters of fact and deduction from historical evidence in the stricter sense Sound as this method may be, it has its obvious limitations When, for example, he deals with the question of land tenure in early Greece, he holds that the whole of the evidence is to be interpreted in favour of individual tenure or, doubtfully at most, tenure on behalf of the *genos* or family group In his opinion, geographical conditions imposed this organisation inevitably on Greece, and the communal tenure of land of primitive man, or even of such social groups as those of Russia, he holds, is not analogous But the literary evidence at best is ambiguous or indecisive, and it would be legitimate to interpret it in the light of what is known of the social system of the invaders from the north in their own land M H Baer in his introduction provides the generalisations on ancient economics from which the author has refrained, but even without these, the book will be for the student a convenient and valuable compendium of the economic and social facts

Introduction to Theoretical Physics By Prof Arthur Haas Translated by Dr T Verschoyle Vol 2 Second edition Pp xi + 492 (London Constable and Co, Ltd, 1929) 21*s* net

THE second edition of Vol 2 of Prof Haas's "Introduction to Theoretical Physics" deserves special mention, because in the four years which have elapsed since the publication of the first English edition (NATURE, vol 117, p 687) great strides have been made in the development of atomic theory The changes in outlook consequent on the introduction of the wave theory of matter and of the new quantum mechanics are reflected in Part III, which has been almost entirely rewritten It is significant of the new point of view that the chapter on the principles of atomic mechanics begins with a description of de Broglie's theory, which is followed by an account of Schrödinger's theory It is not until the following chapter that we meet with a detailed statement as to atomic spectra, and the explanation of the spectrum of hydrogen by means of Bohr's model Prof Haas has written a separate volume on "Wave Mechanics and the New Quantum Theory", in which these subjects are treated at greater length, but it is convenient to have such a concise and clear account of the new developments as that given in the book here noticed

In Part IV, which deals with the theory of heat, several new sections have been supplied, and we have noticed several minor additions to the text which make for completeness There is no doubt that in its revised form the work will meet the needs of many students of physics, and it deserves success H S ALLEN

Greenland (Published by the Commission for the Direction of the Geological and Geographical Investigations in Greenland) Editors Prof M Vahl, Vice Admiral G C Amdrup, Dr L Bobé, Prof Ad S Jensen Vol 3 *The Colonization of Greenland and its History until 1929* Pp v + 468 (Copenhagen C A Reitzel, London Oxford University Press, 1929) 35*s* net

WITH this volume the great work on Greenland, which embodies all available knowledge of the island, is completed An introductory chapter on types of European colonisation is an excellent geographical introduction to a detailed study of the colonisation and trade of Greenland and the economic and social condition of the Greenlanders Little of this matter has been previously accessible in English

Other chapters deal with the status of Greenland in international law and the sanitation and health conditions Admiral Garde discusses the navigation of Greenland waters and gives some indication of the old Norse routes So far as can be judged from scanty directions, the old Norse ships followed courses that are suitable to day, and they afford no evidence of material changes in ice conditions Prof Bøggild adds a short chapter on mining, which relates chiefly to cryolite The volume concludes with an etymological glossary of Eskimo place names, and an index to the folded map of Greenland on a scale of 1 4,000,000 is combined with the index to the three volumes

The British Hydracarina By Chas D Soar and W Williamson Vol 3 (Ray Society Volume No 115, for the Year 1928) Pp viii + 184 + plates 41 60 (London Dulau and Co, Ltd, 1929) 37*s* 6*d*

WE welcome the appearance of Vol 3 of Messrs C D Soar and W Williamson's monograph published by the Ray Society on the British Hydracarina It treats of the remaining species of the subfamily Pioninæ, together with the Aturinæ, Mideopsinæ, and Arrhenurinæ, and at the end of the book there is an index to the genera and species dealt with in the complete three volume series. It is well up to the high standard attained by the Ray Society publications and is profusely illustrated by nineteen plates, of which the first six are coloured Each species is separately figured and there are many illustrations of detailed characters A work of this description which provides a ready means for identification is always a stimulus to the further study of the group concerned, and we trust that it will result in this section of the British mites becoming much better known Workers in the group are very few and far between, and there is a wide scope for the collector to extend our knowledge of the distribution of many of the species and to bring new forms to light

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

School Science and Educational Values

I HAVE no word but of thanks to A A E for his kindly comments in NATURE of Mar 8 upon my articles in the *Kentish Mercury*, yet I cannot but take up the challenge he gives in saying that it can scarcely be supposed that I am attempting to deny the appropriateness of an independent test in helping to determine how a pupil is reacting towards his educational environment Big words these! To me, it seems that there is little *educo* about the business and far too much environment that it is a case of crowding quarts into pints you just test how far the poor little beggar examined happens to be inflated at the moment

I am not clear whether my critic question my denial of the *appropriateness* of any external examination test that may be applied or my objection to *any independent test* I object to both, as physically, mentally and morally harmful to all concerned, to teachers and taught, to parents and examiners The system is of quite recent growth in Great Britain, a modern industry, in fact The men who have made the British Empire have not suffered under it, nor have most of the leaders of to day As the gift of leadership is going from us, we cannot claim that we are now gaining from it Scots have been trained to be efficient, in days gone by, in the smallest country villages, without external interference To day they are officially, hopelessly over examined and by no means so dangerous to the south as they were—the more as they no longer eat oatmeal It is sad that a great people should lose intelligence and individuality through an ill chosen educational test and an attenuated diet The public schools, to save themselves trouble, have adopted a common entrance examination—the result is that the preparatory schools are obliged all to tar with one brush That the product lacks character to day is in no way surprising We do our best to eliminate the quality we most need individuality and strength of character It is a disaster that we no longer trust teachers

The great pioneer of the heuristic method, Mr Squeers, we may be sure, not only taught his boys how to spell 'winders' practically but also himself examined into their being well and truly cleaned he doubtless was careful to drive the whole lesson home his chronicler make no mention of any external examiner The two colleges with which I have been connected, the Finsbury Technical College and the Central at South Kensington, long flourished without external examinations, using material—in my day—which was neither 'matriculated' nor 'school certificated' The Central product had courage, went out into the world and did well to day, I am told, it will not venture abroad

Our bondage comes in large measure from the anti heuristic, unpractical University of London and the wicked example it has set—by opening the matriculation to others than those who were proceeding to its degrees The University of London has lived upon matriculation fees—these are the main support of the large and ever growing army of bureaucratic officials The School Certificate examination is now a most dangerous option to the London Matriculation, as boys may pass it when under fifteen and then specialise

Most unfortunately, the fact is, man cannot let man alone he ever tends mercilessly to oppress the child he never recognises his own great individual ignorance and inability to guide himself, let alone others, through the maze of life He thinks in his own superior terms of disciplined ignorance all the time, not in those of the child's quenchless thirst and desire to develop intelligence

In our gardens, when plants begin to show signs of healthy growth, we do not take them up to examine their roots We regard them lovingly, knowing that if we wish them to flourish we do well to let them alone and merely take care that their surroundings be kept normal and healthy in due course they flower and fruit—we test the fruit by eating it, not by examination The bad is obviously bad Teachers, if and when competent, know full well how far their pupils—to use terms of the phrase rule—are reacting towards their environment Examination tests are advocated, to day, because they give employment to testers I have been eye witness of the insidious rise of the whole system Fortunately, my children have escaped from it but I am obliged to see my grand children suffer

The continued failure of the schools and universities to make proper use of the vast fund of knowledge and experience now available—to be scientific—is by far the blackest sign to day of our inability to avail ourselves of the gift of intelligence the Gods would give us All we can do is to extend the use of machinery and create more and more unemployment soon, we shall examine for this and make the occupation competitive Our own marvellous mechanism is in no way used intelligently We allow those, the merely literary, who have no experimental sense, to govern HENRY E ARMSTRONG

UNFORTUNATELY, I find some difficulty in following Prof Armstrong's argument He complains both that teachers are incompetent and that we do not trust them, both that we fail to apply scientific method to education and that we use similar standards to measure the results of similar experiments by different experimenters Were Prof Armstrong to confine himself to urging far more intimate contact and closer co operation between teachers and examiners (usually themselves teachers) he would, I think, serve the interests of the examined, while preserving our admittedly approximate, but only, method of differentiating degrees of ability Whether or no all independent tests are universally harmful, whether or no examining bodies levy an unjust tax on students, whether or no there is still time to promote fruitfulness when the fruit is ripe, Prof Armstrong provokes us to consider such questions anew Let us apply to them our "vast fund of knowledge and experience", even although he finds that we are ignorant, and that we are unintelligent, a conclusion which the best informed and most sagacious of us will be the last to deny A A E

The Homogeneous Isothermal Reaction $2CO + O_2 = 2CO_2$ in the Presence of Water Vapour

DURING the past two years I have studied the oxidation of carbon monoxide, in silica bulbs, by a manometric method A satisfactory interpretation of the complicated reaction kinetics has not yet been found, but it may be permissible to state in outline the results obtained, since the reaction is of general interest

(1) In a mixture of $CO + O_2 + H_2O$ (0 13 per cent upwards) at total pressures from about 70 mm. upwards,

a homogeneous reaction can be measured in clear silica bulbs, between 530° and 730° C

(2) The presence of water vapour appears to be essential for this reaction there is approximate proportionality between water concentration and velocity for example, at 580°, with excess of carbon monoxide

pH_2O	1 8	6 2	9 0	1[illegible]	mm
velocity	5 3	18 7	25	49	per cent per minute

Using oxygen and carbon monoxide which had stood over phosphorus pentoxide for one day only, the rate was 0 2 per cent per minute at 600° C, while with a mixture which had been standing for several weeks over phosphorus pentoxide the rate first became measurable at about 700° C

(3) The rate (with concentration of water molecules constant) is roughly proportional to concentration of carbon monoxide molecules when oxygen is in excess, and proportional to a power of the concentration of oxygen molecules approximating to zero, when carbon monoxide is in excess, for a given total concentration

(4) The reaction has a chain mechanism, with 'stable' chains at pressures exceeding a certain limit The evidence for this is the increase in temperature coefficient as the temperature rises, and the retardation in a 'packed' bulb with a surface volume ratio increased 18 5 fold

H Kuhl (*Zeit phys Chem*, 44, 385, 1903) studied the oxidation of carbon monoxide in porcelain bulbs, and attributed the irregularity of the results to catalysis by the walls The present results in silica bulbs are rather more reproducible, but it is now clear that the reaction measured by Kuhl must also have been a chain reaction in the gas phase, because of the general similarity of the two sets of results In particular, the rate in comparable reacting mixtures is about the same at the temperature at which Kuhl worked (575° C)

It should be mentioned that the reaction has also been studied by Prof Bodenstein (Bodenstein and Ohlmer, *Zeit phys Chem*, 53, 166, 1905) in silica bulbs, with results completely different from my own Rapid combination was observed at temperatures so low as 318° 230° C It seems most probable (as suggested by Benton and Williams, *Jour Phys Chem*, 30, 1487, 1926) that the reaction was caused by traces of impurity on the walls—a possibility suspected by the authors themselves, in some of their experiments

(5) When a sudden addition is made of oxygen, carbon monoxide, or carbon dioxide to a mixture reacting at a steady rate in the region of the stable chain mechanism, the reaction is retarded in each case, provided that the concentration of water molecules is kept constant If, on the other hand, the *total concentration* of such a reacting mixture is progressively decreased by removal of gas from the bulb, the absolute reaction rate at first decreases, passes through a minimum, and then increases again rapidly, until at a definite concentration inflammation sets in A typical example is that at 570° a $2CO + O_2$ mixture + 2 5 per cent H_2O decreases in rate of combination from 500 mm to a minimum at about 90 mm, and increases again rapidly to a critical pressure of 65 mm, at which the mixture explodes

(6) The reaction in the stable chain region is accompanied by a violet glow I am indebted to Mr. A L Carrad for the following observation the glow, observed in a wide quartz tube with a quartz window, at 570° C, becomes more intense as the reacting gas is pumped out of the tube, until near the critical pressure a rapid increase in brightness culminates in a vivid flash. Thus the inflammation at this (upper) critical pressure completes a region of increasing velocity, and may therefore be a case of thermal acceleration following upon the increase in velocity which arises in the first place from diminished deactivation of reaction chains in the gas phases

In a recent paper Prof Semenoff and co workers (*Zeit phys Chem*, B, 6, 307, 1930) have investigated carefully the upper and lower pressure limits for inflammation of $CO + O_2$ mixtures expanded from a mixture originally saturated with water vapour So far as my own observations go (made upon the upper limit only), the results agree with those already published by Prof Semenoff, in addition, I find that both the existence of the critical limit for inflammation and the behaviour of the 'slow' homogeneous reaction described in paragraphs (5) and (6) are dependent upon the presence of a sufficient proportion of water vapour, otherwise the reaction rate decreases continuously as the total concentration is reduced, and there is no minimum and no inflammation

It has been shown by Prof Garner ("The Initiation of Flame in Mixtures of Carbon Monoxide and Oxygen", Garner and Gomm *Trans Farad Soc*, 24, 470, 1928) that the *lower* pressure limit for inflammation (5 10 mm total pressure, from 660° to 850° C) is the same whether the original mixture is dried by passage over 10 cm of phosphorus pentoxide, or is saturated with water vapour This is interesting and unexpected in view of the dependence of the *upper* pressure limit and the 'slow' homogeneous reaction upon water vapour concentration

(7) I have once or twice encountered an induction period prior to explosion, under conditions similar to those of the following instance 258 mm carbon monoxide, roughly dried by phosphorus pentoxide, added to 118 mm oxygen similarly dried, remained quiescent for 2 minutes and then exploded

A point which I hope to decide by further experiment upon this phenomenon and the general kinetics of the 'slow' homogeneous reaction is whether the initiation of the reaction chains involves the silica surface, through the catalytic effect upon the water gas reaction, with H_2, and H_2O_2 or OH as links in the chain

Group Velocity and Wave Mechanics

IF it be true that Nature is built up not of particles but of waves, it is obviously of great importance to gain clear ideas as to the characteristics of wave motion In dealing with any oscillatory motion, Dr Albert Campbell suggested several years ago the use of the term *pulsatance* (an alternative form some times used is *pulsance*) for $2\pi\nu$ where ν is the frequency (*Proc Phys Soc*, vol 31, p 80, 1919) Thus the pulsatance is the number of vibrations in 2π units of time I have found this term of very great service in teaching, as it economises time in discussion and space in writing or printing Even the elementary student appreciates its value when he recognises that it corresponds to angular velocity in the reference circle in defining simple harmonic motion Such a motion is represented by the equation $y = A \sin pt$, where A is the amplitude and p the pulsatance

Similarly, in discussing wave motion, it is convenient to introduce a quantity expressing the number of waves, each of wave-length λ, in 2π units of length I propose, tentatively, to call this quantity $k = 2\pi/\lambda$, the *undulatance* The equation for the simplest type of wave motion, the progressive harmonic wave, is now $y = A \sin (pt - kx + \epsilon)$ The phase of the wave motion is determined by $\phi = pt - kx + \epsilon$, and the phase velocity, $u = p/k$, is obtained by dividing

the pulsatance by the undulatance This follows from the fact that if we substitute $t+t'$ for t, and $x+\frac{p}{k}t'$ for x, the equation is unchanged in form

The discussion of group velocity (see, for example, Sommerfeld, "Wellenmechanischer Ergänzungsband", or Haas, "Wave Mechanics", Chap ii) may now be abbreviated as follows When there is approximate agreement of phase among the waves belonging to a group, the resultant vibration is relatively large The 'centre of energy' of the wave group is characterised by the fact that the partial differential coefficient of the phase with respect to the pulsatance must vanish, or $\partial\phi/\partial p=0$ This condition results in the equation $x=\frac{dp}{dk}\left(t+\frac{d\epsilon}{dp}\right)$, showing that the centre of energy moves with a velocity g, the group velocity, given by $g=dp/dk$ (Rayleigh, "Theory of Sound", vol 2, p 297) This leads quite simply to the more familiar expressions for the group velocity in terms of frequency (de Broglie) or wave length

Assuming that a mass particle, m, moving with velocity v is associated with a system of waves, it can be shown by employing Einstein's principle that the phase velocity $u=p/k=c^2/v$, and is accordingly greater than c, the velocity of light The pulsatance p is related to the pulsatance p_0 referred to a system of co ordinates moving with the body by the Lorentz equation $p=p_0(1-v^2/c^2)^{-\frac{1}{2}}$, so that $p^2(1-v^2/c^2)=p_0^2$, or $p^2-c^2k^2=p_0^2$ From this we find $g=dp/dk=c^2k/p=v$, and so we see that v the particle velocity is the same as the group velocity g

It will be seen that this derivation of the result is shorter and more direct than that usually given, although there is nothing essentially new in the method The phraseology here suggested will be found useful in dealing with the wave mechanics of Louis de Broglie and of Schrödinger

In this connexion it may be pointed out that it would be a great convenience in theoretical work to have a recognised symbol to represent $h/2\pi$, the quantum unit of angular momentum A small letter, not a capital, is desirable, and after considering various possibilities, it is suggested that the letter b may be suitable We should then write $b=h/2\pi$ and the fine structure constant would be given by $\alpha=e^2/bc$ According to Eddington's recent calculation $bc/e^2=137$ The letter b may serve to recall the name of Niels Bohr, although it should be remembered that J W Nicholson was the first to employ the quantity $h/2\pi$ in his work on the spectra of nebulæ and the solar corona (1911–12)

The Acquired Characters of *Alytes*

THE reading again, after many years, of von Nägeli's account of his experiments with Alpine plants[1] has suggested to me the possibility that Kammerer's experiments with *Alytes* may have no bearing upon the inheritance of acquired characters, even if we accept all the results he claimed, and all that others have claimed on his behalf

May I give a very brief sketch of von Nägeli's experiments? He took some Alpine plants from their ordinary surroundings and placed them in rich soil, under the usual conditions of cultivation, in the Botanical Gardens at Munich The plants thus removed from their normal environment changed in their characters so much that, had he not seen the transformation taking place, von Nägeli would not have recognised them The seeds of these plants grown in the Botanical Gardens under the same conditions, reproduced the characters that their parents had developed under cultivation, and this went on for about thirteen years But when, at the end of this period, some of the plants were removed to poor and stoney soil, they reverted to the characters of their Alpine ancestors, which characters had not appeared for all these generations Moreover, the seeds of the plants in the Botanical Gardens when grown under Alpine conditions produced the characters of their comparatively remote ancestors and not those of their parents for thirteen generations back

A comparison of this with what happened in Kammerer's *Alytes* is, I think, very illuminating *Alytes* and its young pair, hatch out and live on land, and, though the embryo has a gill, it loses this before coming out of the egg The male *Alytes* does not develop the nuptial pad present in other toads and in frogs, such a pad would be useless to it When, however, *Alytes* was kept warm and given free access to water in sufficient quantity, a change in several of its characters was produced Pairing took place in the water, and the eggs, after fertilisation, instead of being carried about by the male, were deposited as are those of other allied species and genera The larvæ from these eggs, hatched out in the water, had gills The males, it is stated, developed nuptial pads similar to those of other male toads and frogs, though these pads were imperfect, and this continued in succeeding generations

But—and this is to me the crucial point—all the subsequent generations were given free access to water Indeed, had they not been able to breed in the water, several of these changes of character must have proved fatal to the offspring

The question is whether, had these subsequent generations of *Alytes* been deprived of access to water, they would not have reverted to the characters of their ancestors, including the disappearance of the nuptial pads? I gather that nothing of this kind has been tried, and until it is, these new characters appear to me to mean no more than did the new characters of von Nägeli's Alpine plants What happened in both cases may be explained most simply by the presence in the germ plasm of potentialities to respond in a definite manner to changes in the environment, and to me the simplest explanation appears most likely to be true Any other would require quite unnecessary assumptions

Until, therefore, some enterprising biologist who has the facilities, completes the experiment as I have suggested, the question must remain open My personal belief is that the answer will be that *Alytes* will behave much as did the Alpine plants It would be too much to expect that the two cases would be parallel in detail, but I suggest that the general result will be the same

A Singular Behaviour of Striæ in the Positive Column of an Electrical Discharge through Hydrogen

THE following behaviour of some striæ in the positive column of an electrical discharge through rarefied hydrogen seems to be of sufficient interest to warrant a description The distances between adjacent striæ in hydrogen change with gas pressure in an anomalous manner first noted by Willows (*Proc Camb Phil Soc.*, **10**, 302, 1900), in that, with reduction of pressure,

they at first increase in magnitude, pass through a maximum value and then in turn through a minimum value. This minimum occurred at about 1·5 mm. pressure in the discharge tubes I used, which had an internal diameter of 11 mm. The striæ here were bluish in colour, whereas at the other pressures their colour was reddish. The phenomenon to be described was only observed in this narrow pressure region where the striæ were most closely packed. The discharge current was kept constant at 6 milliamperes and it passed between cold electrodes consisting of aluminium cylinders 2 mm. in diameter.

When the critical pressure was reached, a very slight reduction of pressure caused the stria nearest the cathode to leave the positive column and move slowly across the whole Faraday dark space up to and beyond the end of the cathode. Here it remained as a distinct band of light encircling the cylindrical cathode. During all this time the remainder of the positive column remained unchanged in position. A further reduction of pressure caused a second stria to detach itself from the positive column and in turn to proceed slowly up to the cathode and to merge there with the first stria. A still further reduction of pressure often made a third stria repeat the performance of the first two. When the pressure was now very slowly increased the reverse process took place, one of the striæ detached itself from the band of light around the cathode containing the merged striæ and marched slowly back until it resumed its original place in the positive column. Then in its turn the second stria, and finally the third, did the same thing. The whole procedure could be repeated at will.

No explanation of this curious behaviour of these striæ has been found. It is known that the electric field throughout the Faraday dark space is very small compared to the average field prevailing in the positive column. The existence of this dark space seems to be dependent upon a copious supply of electrons coming from the negative glow as well as upon electric charges on the walls of the discharge tube. The Faraday dark space is thought of as a unit, the cause for the existence of which proceeds from the cathode. How, then, is it possible to divide this region of low field intensity into two parts by the intrusion of a stria with its presumably much larger fields? In other words, when the Faraday dark space has once terminated at the isolated stria, what brings it into existence again beyond this stria? It would appear that conditions at the surface of the walls of the tube play a large rôle in the phenomenon described, and that these conditions are markedly affected by a slight change of pressure at the critical value here involved.

Other observers have remarked upon the fact that at a certain pressure the discharge through hydrogen undergoes a sudden change during which a number of the striæ from the end of the positive column jump to the cathode. The observations noted above show that the change is not a discontinuous one, but that during a very slow reduction of pressure the whole process may be followed continuously in detail.

Mounting Media for Microscopic Work

IN the examination of colourless transparent objects under the microscope, it is important to have sufficient difference of refractive index between the objects and the mountant to retain visibility of outline under critical conditions of illumination. In addition to this, it is essential that there shall be no effect on the structure of the preparation, such as the swelling produced in some dehydrated materials by aqueous mountants. To fulfil these conditions I prepared a new medium with a cellulose ester base, the refractive index of which could be varied within quite wide limits (n = 1·45 to 1·57) by the addition of a plasticiser of suitable refractive index and a volatile solvent to dissolve the mixture.

A medium giving a refractive index of 1·42 when liquid, rising to 1·47 when hard, which is very useful for unstained cellulose materials (n – 1·52 to 1·54), has the following percentage composition:

Cellulose nitrate (extra low viscosity type—Nobel's H X 2)	25
Triacetin	25
Methyl ethyl ketone	50

Mixed together and stirred until dissolved.

The medium is applied in the same manner as Canada balsam and allowed to harden either with or without heat. During the hardening process the ketone evaporates and the refractive index rises from the lower to the upper value.

The refractive index data of other media in which various plasticisers have been substituted for triacetin, but without any other change, are given below, together with comparative values for euparal and Canada balsam resins. It will be seen from the table that these new media give a considerably extended range, from which in most cases a suitable one may be chosen, though there are naturally many others available.

Mountant	Refractive Index	
	Liquid	Hardened
Cellulose nitrate, methyl ethyl ketone and		
Triacetin	1·417	1·471
Resorcinol diacetate	1·435	1·517
Benzyl alcohol	1·442	1·525
Tricresyl phosphate	1·448	1·545
Benzophenone	1·461	1·573
Euparal	1·481	1·525
Canada balsam (Xylol)	1·530	1·545

Cellulose acetate can be used in place of cellulose nitrate and is found to give somewhat lower values of the refractive index with the same plasticiser. However, in the case of the acetate, more dilute solutions must be used in order to obtain a sufficiently fluid medium.

THE mountant suggested by Mr. Edwin E. Jelley in NATURE of Feb. 22 raises some points of interest. Visibility of uncoloured microscopical objects is dependent on a difference in refractive index between the object, or any part of it, and its environment, usually a mountant. The principles involved were expounded for petrological specimens by Mr. Sorby and for diatoms by Mr. Stephenson fifty years ago.

Many mountants have been tried for diatoms, and I. D. Möller especially mounted some of his type slides in mono brom naphthalene. One, belonging to the Geological Department of this University, now shows minute globules, probably aqueous, on the under surface of the cover glass. Theoretically there appears to be little advantage in Mr. Jelley's mountant for diatoms and crystals. If a slide with such a mountant is not rung with a suitable protective, evaporation of the mono brom-naphthalene will slowly occur and

eventually the mountant will be simple Canada balsam If the slide is to be rung, it would generally be better to mount in the brom naphthalene alone and thus obtain the advantage of a higher refractive index Should, however, such a mixture be required, styrax, which is also soluble in mono-brom naphthalene and has a higher refractive index than Canada balsam, would generally be a preferable ingredient A workable combination has a refractive index of 1 62

In October of last year I carried out an investigation on the influence of the refractive index of mountants on biological tissues which I hope shortly to publish Tissues were mounted in media of varying refractive index from 1 34 to 2 1 (phosphorus) The mountant of highest refractive index that could be conveniently used was a saturated solution of sulphur and arsenious sulphide in methylene iodide Such a mixture is of a canary yellow colour and has a refractive index of 1 804 It is apparently stable, since it has been kept in an open test tube, apparently unchanged, for five months Mounts in this liquid, however, need ringing A higher refractive index, namely, 1 87, is obtained with a solution of phosphorus in methylene iodide, but the golden yellow liquid soon becomes cloudy on exposure to air

Isolation of the Radical Ethyl

We have been successful in preparing the free radical ethyl (in the same way as we obtained the free methyl) by decomposing lead tetraethyl in a hydrogen stream at reduced pressure by means of heat (compare Paneth and Hofeditz, *Ber Deuts Chem Gesells*, 62, 1335, 1929 Nature, 124, 161, 1929) The free ethyl is not less aggressive than the free methyl It converts the metals zinc, cadmium, antimony, and lead into volatile compounds which (under atmospheric pressure and at room temperature) form limpid liquids The zinc compound has been studied in some detail the presence of ethyl could be established by converting the ethyl groups into alcohol and identifying the latter by the iodoform test, the metal revealed itself as zinc free from lead, and the melting and boiling point of the compound coincided with those known for zinc diethyl As the zinc metal before conversion into this compound had been located at a distance from the place of decomposition of the lead tetraethyl, it seems to be demonstrated that the radical ethyl can be obtained in the free state and carried by a gas stream over several centimetres before recombination takes place

A fuller report of the experiments on free ethyl will be published in the *Berichte der Deutschen Chemischen Gesellschaft*

The Maladaptation of Trout Spermatozoa to Fresh Water

The finding of Prof Huxley (Nature, Mar 29) that the addition of salts to fresh water prolongs the period of activity of trout spermatozoa confirms results of other workers There are several papers bearing on this subject, but those of Scheuring [1] [2] and Gaschott [3] treat specifically of the spermatozoa of the trout and salmon Analogous results have been obtained with amphibian material, and it is perhaps general that an osmotic pressure approximating to that of the tissues is favourable to the maintenance of the integrity of the cell, notwithstanding the fact that fertilisation may normally take place in a hypotonic medium The problem is, however, not a simple one, and the specific effect of various solutes, more particularly their ions, on the cell must be taken into consideration

Apart from the problems of physiological interest which are raised, the results have, as Prof Huxley suggests, an interesting bearing on the evolution of species in their transition from marine to estuarine, fluvial, and terrestrial forms The necessity for a reduction in the time of exposure of the gametes or their protection from the external environment is perhaps reflected in many modifications of sexual mechanisms and behaviour Copulation with internal fertilisation is the most complete solution of the difficulty At present I am collecting references and experimental data which I hope will enable me to write more explicitly on the subject in the near future

Mating during Pregnancy in the Mouse

It would seem that mating during pregnancy in the rat and mouse is an exceedingly rare occurrence Nelson (1929) [1] has recorded one instance in the rat, and Long and Evans (1922) [2] refer to two others So far as we know, mating during pregnancy has not been recorded in the case of the mouse It seems worth while to place on record, therefore, the following facts which have presented themselves to our notice during the course of an experiment in which 100 females have been examined daily for six months for vaginal plugs—evidence of mating The animals were continuously kept with males so that every opportunity for mating was given

Date when 1st Vaginal Plug was noticed	Date when 2nd Vaginal Plug was noticed	Date of Parturition	Number in Litter	Number of Days between 1st and 2nd Vaginal Plugs
22 8 29	7 9 29	10 9 29	4	16
5 8 29	9 8 29	24 8 29	6	4
2 10 29	12 10 29	21 10 29	8	10
20 9 29	5 10 29	10 10 29	8	15
27 10 29	5 11 29	15 11 29	8	8
25 12 29	8 1 30	12 1 30	5	14

In our experience, then, out of 100 females under observation for six months, 6 presented trustworthy evidence that during pregnancy mating had occurred without in any way affecting the course of pregnancy It is seen that during the course of a single pregnancy mating occurred only once in our experience, and that it occurred not always at the same time during pregnancy though always at a time when, had the animal not been pregnant, it would have been expected

Reaction of the Phagocytes of Arthropods to their Internal Insect Parasites

By Dr W R THOMPSON, Imperial Bureau of Entomology

IN his celebrated work on the pathology of inflammation, first published in 1892, E Metchnikoff[1] made a general survey of the phenomena of phagocytosis in the animal kingdom and pointed out that there exist between the various groups very striking differences in the behaviour of the white blood cells towards internal parasites He stated that among the Arthropods the phagocytic reaction is, in general, rather feeble, and suggested that this condition is perhaps related to the development of a chitinous cuticula in these animals, and that since this cuticula prevents the entrance of parasitic organisms the defensive activity of the phagocytes is less marked than in organisms which do not possess this protection Several years later L Cuénot, in his "Études sur la physiologie des orthoptères", criticised the views of Metchnikoff on the ground that the cuticular armature of the Arthropods, in spite of its thickness, is a very inefficient means of defence against parasites Cuénot had, indeed, observed that the parasites of Arthropods in their habitual hosts are not usually attacked by phagocytes, but he explained this fact on the hypothesis that the parasites have developed the power of resisting the phagocytes, by which they would otherwise be destroyed According to this idea, when a new parasite arrives in an Arthropod it ought to be attacked by the phagocytes and destroyed by them

In a later paper Cuénot[2] modified these views to some extent, having found that living parasites of Arthropods may be surrounded by the blood cells, although the encystment has not, necessarily, a fatal result Cuénot did not, however, put forward any satisfactory evidence for the view that the insect parasites of Arthropods are ordinarily attacked by phagocytes when in a healthy and living condition

In his admirable studies of the biology of the Diptera parasitic on insects (1898, 1910), J Pantel,[3] whose conclusions were based on the study of a large number of species, stated that as a general rule the free and healthy larvæ of entomophagous parasites are not attacked by phagocytes The phagocytes of the infested organism, according to Pantel, are always inactive in relation to normal parasites They intervene in cases of bacterial infection by the integumental sheath and accumulate about sick or dead parasites or moult skins

The results of my own studies on this subject, of which a summary up to that date was published in 1915,[4] confirm those of Pantel Nevertheless, the view that even in Arthropods the phagocytes constitute a defensive mechanism against parasitic enemies of all kinds, that the destruction and death of parasites entering hosts to which they are not adapted is due to phagocytic attack, and conversely, that the process of adaptation to a specific host consists essentially in the elaboration by the parasite of anti-phagocytic secretions or the development by it of structures constituting a defence against the blood cells, still continues to be advocated To give only one example, this is the view put forward by Caullery[5] in his book on parasitism and symbiosis (chap x p 250) It seems, therefore, desirable to give a brief general summary of the facts concerning the tissue reactions of Arthropods to their internal insect parasites No attempt will be made in this article to discuss the relation between the blood cells of Arthropods and protozoan, fungous, or bacterial parasites, because the physiological relations between these organisms and the hosts they infest are very different from the relations between internal insect parasites and their hosts

Taking, then, the internal insect parasites of Arthropods, which infest their hosts, for the most part, in the larval condition, we may classify them according to the exact nature of their relations with their hosts into three principal groups

1 The first group includes those parasites the larvæ of which lie free within the body cavity of their host To this group belong the vast majority of the internal Hymenopterous parasites and a minority of the Diptera So far as I have observed, the living larvæ of parasites of this group are never attacked by phagocytes There is no particular reason to suppose that they *repel* the phagocytes The phagocytes seem simply to be *indifferent* to the parasite larvæ as they are to the organs of the host itself

2 The second group comprises the parasites which penetrate into some organ of the host, in which they pass a considerable period without, however, causing any extensive and rapid destruction of tissue Examples of this type are the Diptera *Sturmia scutellata* R D, which lives during the first larval stage in the muscle fibre of the caterpillar which it infests, *Sturmia sericariæ* Corn, the parasite of the silkworm, which lives in a ganglion of the ventral nerve chain of the host, and *Blepharidopsis nemea* Meig, which lives in a lobe of the fat body The larvæ of these species develop slowly, absorbing nutriment from the organs into which they have penetrated, and sometimes cause marked pathological changes, but no rapid and extensive destruction of tissue The reactions produced in the host tissue which they enter are in no way either advantageous to the host itself or detrimental to the parasite, on the other hand, no phagocytic accumulations are formed around the bodies of these larvæ

3 The third group of parasites includes species which enter into anatomical relations with the host in such a way that extensive and sometimes rapid destruction of tissue is produced Such are the numerous Tachinids which enter the body of the host through the skin and leave the extremity with the posterior spiracles embedded in the body-wall, and those which after entering force the posterior extremity either into the lumen of a trachea or through the body-wall in order to obtain access to the outer air. The Tachinid, *Plagia trepida* Meig, which enters a muscle fibre in the first larval stage and immediately begins to devour the muscular substance, can also be placed in this group Around

larvæ of this kind, or adjacent to them, accumulations of phagocytes are frequently observed These accumulations appear to depend upon the diffusion into the blood of substances from the destroyed tissues, or, as Pantel suggests, on the diffusion of toxins from bacteria which have penetrated into the body of the caterpillar through the opening made by the parasite Sometimes the accumulations of phagocytes are very extensive and completely surround the parasite, but they never penetrate into its body, nor is there any good evidence that they impede its development

The statements just made summarise the data in what may be called cases of natural parasitism As will be seen, they afford no support for the view that the adaptation of the internal insect parasite to its host consists essentially in the development of substances destined to repel the phagocytes, or in structures designed to afford protection from their attack To test this point, I carried out several years ago a number of experiments, during which I introduced into the body cavity of living insects sarcophagous or parasitic larvæ, which are never found in the species concerned in Nature In some of these experiments the parasites introduced into the unfamiliar hosts lived and developed in the normal way, and in that case were never molested by the phagocytes In other cases they died and the phagocytes gathered around their bodies except when the host was in a very diseased or exhausted condition, but in no case was any accumulation of phagocytes observed around a living parasite The results of these experiments were confirmed by others, in which the larva of the internal parasite was killed without wounding the host, by blocking up the opening of its respiratory funnel No accumulation of phagocytes around the parasite larva was observed in such cases so long as it remained alive, but after its death, blood cells began at once to accumulate about it

It has long been known that phagocytes become extremely abundant during the pupal period and are found during this time migrating into and destroying the degenerating larval tissues, but there is no reason to suppose that this period is especially dangerous for internal parasites, or that they require any protective secretions or structures in order to enable them to survive it *Chalcis Fonscolombei* Duf, the parasite of Sarcophagids, which attacks its host during the late larval stage and emerges from the puparia, does not possess any sack The same thing is true of *Alysia manducator* Panz, the Braconid parasite of *Lucilia sericata* Meig On the other hand, there is no reason to suppose that the trophamnion which occurs in some pupal parasites is a protection against phagocytic attack, for there are many parasites which live within a membrane of this type, but infest their host only during the larval period, as, for example, the polyembryonic Encyrtids

Finally, the idea that phagocytes break down the tissues of the parasites they attack and that the substance of the latter is built up into the tissues of the host, seems also to be contrary to the facts The accumulation of phagocytes about the body of a dead parasite appears to continue for a considerable time, but it is not certain that the phagocytes ever disperse Dead eggs or larvæ may often be found many months after their death has occurred, surrounded by a dense ball of phagocytes, many cells thick, of which the internal layers show manifest signs of cellular degeneration Within these balls the dead larvæ disintegrate, but the action of the autolytic enzymes would produce this effect without the intervention of the phagocytes, which do not, so far as I have observed, actually penetrate into the bodies of the parasites

Clerk Maxwell and the Michelson Experiment

We have received from Mr. Rollo Appleyard, author of "Pioneers of Electrical Communication", a copy of correspondence that he has had with Prof P Lenard, of Heidelberg, on the association of Clerk Maxwell with the Michelson experiment Prof Lenard suggested that although it is universally acknowledged that Maxwell played an important part in instituting the inquiry, it would be helpful if references could be obtained to Maxwell's own account of his views Mr Appleyard accordingly furnished the following particulars, which Prof Lenard requested might be published in Nature, in order that full credit might be given to Clerk Maxwell for the part he took in inspiring the Michelson experiment

At a meeting of the Royal Society on Jan 6, 1880, Prof G Stokes, the secretary, communicated a paper by Prof Clerk Maxwell, who had recently died, the paper was a letter to Prof D P Todd, who was then Director of the American Ephemeris This letter suggested that careful observations of the times of the eclipses of Jupiter's satellites, when Jupiter was in different directions as seen from the earth, might show whether the velocity of light varied in different directions, owing to the motion of the solar system through the ether Clerk Maxwell admitted that he was not an astronomer, and was doubtful whether the eclipses could be timed with sufficient accuracy to test the suggestion He thought it would probably be agreed that the only class of observations that would be of sufficient accuracy for the purpose would be the photometric ones that were made at Harvard College Observatory, or others on similar lines Even with these Prof R A Sampson found puzzling anomalies, due perhaps to changes in the character of Jupiter's surface, which is of a cloudy nature, and apparently subject to variations in its transparency

Clerk Maxwell had thought that terrestrial ex-

periments would be useless to solve the problem, owing to the extreme smallness of the quantity to be measured, which is one of the second order However, his letter led to an article by Prof A A Michelson, which appeared in the *American Journal of Science* for August 1881, extracts from which are printed below It will be seen that Michelson refers to Maxwell's suggestion, and notes that the second order quantity, which Maxwell had considered too small to determine, is "easily measurable" He then gives an outline of what we now know as the Michelson experiment

Clerk Maxwell's name therefore deserves mention, since apparently his suggestion, though not fruitful in the manner that he hoped, had some effect in bringing about the famous experiment, the result of which laid the foundation of the theory of relativity

---

Extract from *American Journal of Science*, Series (3), Vol 22, p 120, August 1881

Art XXI —*The Relative Motion of the Earth and the Luminiferous Ether*

By Albert A Michelson, Master, U S Navy

Let V be the velocity of light

v = the speed of the earth with respect to the ether

D = the distance between the two points

d = the distance through which the earth moves while light travels from one point to another (on the earth's surface)

d_1 = the distance earth moves while light passes in the opposite direction

Suppose the direction of the line joining the two points to coincide with the direction of earth's motion and let

T = time required for light to pass from the one point to the other, and

T_1 = time required for it to pass in the opposite direction Further, let

T_0 = time required to perform the journey if the earth were at rest

Then

$$T=\frac{D+d}{V}=\frac{d}{v}, \quad \text{and} \quad T_1=\frac{D-d}{V}=\frac{d_1}{v}$$

From these relations we find

$$d=D\frac{v}{V-v}, \quad \text{and} \quad d_1=D\frac{v}{V+v},$$

whence

$$T=\frac{D}{V-v} \quad \text{and} \quad T_1=\frac{D}{V+v},$$

$$T-T_1=2T_0\frac{v}{V} \text{ nearly, and}$$

$$v=V\frac{T-T_1}{2T_0}$$

If now it were possible to measure $T-T_1$, since V and T_0 are known, we could find v, the velocity of the earth's motion through the ether

In a letter, published in NATURE shortly after his death [read before the Royal Society on Jan 6, 1880, see NATURE, Jan 29, 1880, p 314], Clerk Maxwell pointed out that $T-T_1$ could be calculated by measuring the velocity of light by means of the eclipses of Jupiter's satellites at periods when that planet lay in different directions from earth, but that for this purpose the observations of these eclipses must greatly exceed in accuracy those which have thus far been obtained In the same letter, it was also stated that the reason why such measurements could not be made at the earth's surface was that we have thus far no method for measuring the velocity of light which does not involve the necessity of returning the light over its path, whereby it would lose nearly as much as was gained in going The difference depending on the square of the ratio of the two velocities, according to Maxwell, is far too small to measure

The following is intended to show that with a wave-length of yellow light as a standard, the quantity—if it exists—is easily measurable Using the same notation as before, we have—

$$T=\frac{D}{V-v}, \quad \text{and} \quad T_1=\frac{D}{V+v}$$

The whole time occupied therefore in going and returning [is]

$$T+T_1=2D\frac{V}{V^2-v^2}$$

If, however the light had travelled in a direction at right angles to the earth's motion it would be entirely unaffected, and the time of going and returning would be therefore

$$2\frac{D}{V}=2T_0$$

The difference between the times $T+T_1$ and $2T_0$ is

$$2DV\left(\frac{1}{V^2-v^2}-\frac{1}{V^2}\right)=\tau,$$

$$\tau=2DV\frac{v^2}{V^2(V^2-v^2)} \text{ or nearly } 2T_0\frac{v^2}{V^2}$$

In the time τ the light would travel a distance

$$V\tau=2VT_0\frac{v^2}{V^2}=2D\frac{v^2}{V^2}$$

That is, the actual distance the light travels in the first case is greater than in the second, by the quantity $2D\frac{v^2}{V^2}$

Considering only the velocity of the earth in its orbit, the ratio

$$\frac{v}{V}=\frac{1}{10,000} \text{ approximately, and}$$

$$\frac{v^2}{V^2}=\frac{1}{100,000,000}$$

If D = 1200 millimetres, or in wave lengths of light, 2,000,000, then in terms of the same unit,

$$2D\frac{v^2}{V^2}=\frac{4}{100}$$

If, therefore, an apparatus is so constructed as to permit two pencils of light, which have travelled over paths at right angles to each other, to interfere, the pencil which has travelled in the direction of the earth's motion, will in reality travel $\frac{4}{100}$ of a wave-length farther than it would have done were the earth at rest The other pencil being at right angles to the motion would not be affected

In conclusion, I take this opportunity to thank Mr Graham Bell, who has provided the means for carrying out this work, and Professor Vogel, the Director of the Astrophysikalisches Observatorium [in Potsdam], for his courtesy in placing the resources of the laboratory at my disposal

Radio Direction-Finding by Transmission and Reception *

By Dr R L Smith Rose

Transmission Over Sea and Night Error

WHEN the transmission is entirely over sea the minimum range for night errors to be experienced is increased to about 100 miles due to the diminished attenuation of the direct wave resulting from the superior conductivity of sea water At distances greater than the minimum already mentioned the errors increase in magnitude for distances up to a few hundred miles When the distance is very great it is possible for much of the downcoming radiation to arrive at a very large angle of incidence For example a section of the earth and the ionised layer drawn to scale is shown in Fig 4 From this it is evident that at distances of 1780 and 3560 miles it is just possible for radiation leaving the transmitter horizontally to return to the earth s surface at grazing incidence It is likely that the intensity of such waves after two reflections from

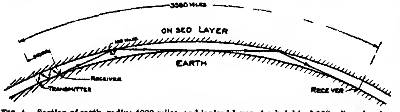

FIG 4 —Section of earth radius 4000 miles and ionised layer at a height of 100 miles showing the paths of waves from a transmitting station and two receivers at distances of 240 miles and 3560 miles

the ionised layer and one from the earth s surface will be much greater than that of waves which have undergone a greater number of reflections and thus it is the downcoming wave arriving horizontally which will be chiefly responsible for the received signal intensity It is evident that only small variations in direction finder bearings will be expected under such conditions

Now the distance of 3500 miles is approximately that between the National Physical Laboratory Teddington and some of the high power transmitting stations in the United States of America A series of systematic observations carried out on two of these stations operating on wave lengths of 16 4 km and 16 8 km showed that the proportion of bearings correct to within 2° was 100 per cent in one case and 94 per cent in the other the maximum error in the second instance being 3 4° Under similar conditions observations made on several European transmitting stations using wave lengths between 14 km and 19 km at distances of 75—760 miles showed maximum errors in bearings of 12° to 28° while the proportion of bearings correct to within 2° was only 16—63 per cent Reference to Fig 4 shows that this result is to be expected since at a range of 240 miles for example the angle of incidence of waves arriving at the receiver after two deflections from the ionised layer is of the order of 35°

* Continued from p. 532

Elimination of Night Errors in Direction Finding

It will be evident that any receiving system which is unaffected by horizontal components of electric force will be free from night errors even though the vertically polarised downcoming waves still produce variations in received signal strength A direction finding receiving arrangement which fulfils this condition was patented by Adcock in 1919 but it does not appear to have received practical consideration until Mr Barfield and I experimented with it in 1926 The simplest form of the Adcock aerial system is a pair of spaced vertical aerials arranged to rotate about a central vertical axis thus forming the equivalent of the single closed coil direction finder By making all connexions to the centres of the aerials the horizontal members of the system are compensated so that no electromotive force is induced in the receiver by a horizontal electric force Preliminary tests with this direction finder carried out a few years ago showed that the system was effective in considerably reducing the magnitude of the night variations experienced with the closed loop system The continued development of the system as a practical form of direction finder free from night errors is still in progress

The Rotating Loop Beacon

As an alternative to the direction finding schemes outlined above the directional part of the wireless system may be transferred from the receiving to the transmitting end This is effected in the rotating loop beacon system developed by the Royal Air Force which employs a vertical closed loop transmitter arranged to rotate about a vertical axis at a uniform speed of one revolution a minute As the loop rotates the field radiated in any given direction varies according to a cosine law passing through successive maximum and minimum values at intervals of 15 seconds When the plane of the loop is perpendicular to the geographical meridian a characteristic signal is emitted by the beacon which may be termed the north point The observer at a distant receiving station upon hearing this signal starts a chronograph As the beacon rotates the intensity of the received signal varies and will ultimately pass through a minimum or zero at which instant it is known that the plane of the transmitting loop is at right angles to the great circle through transmitter and receiver If the reading of the chronograph is observed at this instant of minimum signal intensity it is evident that the bearing of the transmitter from the receiver can be obtained from a simple calculation

It is to be noted that since the radiation from the coil is symmetrical about its plane, a second minimum will be obtained after a rotation of 180° from the first. With the beacon making one revolution per minute, therefore, a line bearing is obtainable in the above manner every half-minute. To fix the position of a receiving station it is necessary to obtain line bearings from two or more beacons. Since the timing process mentioned above is but an intermediate step in taking a bearing, it is convenient to provide a stop watch or chronograph for the purpose, with a dial specially engraved in degrees and points of the compass.

An application of the principle of reversibility in direction-finding makes it evident that the performance of a rotating loop beacon transmitter can be largely predicted from the results and experience obtained with receiving loop direction finders. Thus, a rotating loop beacon when erected on the same site as the direction finder will give observations at a distant receiver which will be subject to the same type of local error and night variations, for example, as the bearings observed on the direction finder when the distant receiving aerial is used for transmission. I have confirmed these deductions in the investigation during the past two or three years, of the performance of a rotating beacon erected at Fort Monckton, near Gosport. In order to ascertain the trustworthiness of this type of rotating beacon as an aid to marine navigation, a number of tests were carried out in ships crossing the English Channel between Southampton and Havre, and Southampton and Jersey. Using the ship's ordinary wireless receiver, observations of the bearing of the beacon were made at intervals during each trip and compared with the bearing as given by the captain of the ship.

As a result of tests conducted on these lines, it was found that in the majority of cases the estimated and observed bearings agreed to within from 2° to 4°. Signs of night effects in the shape of indistinct signal minima and wandering bearings were observed at ranges exceeding 60 miles. In many cases at night and during misty weather when visibility was very poor, the ship was navigated by dead reckoning, and in these circumstances it was frequently considered that the bearing obtained from the rotating beacon was the more accurate. Some of the test runs made between Southampton and Jersey were carried out in a ship fitted with a direction finder of the Marconi Bellini-Tosi type, and the opportunity was thus provided of comparing the two systems of obtaining wireless bearings under actual sea going conditions. The observations carried out in this manner showed that in the majority of cases the bearings obtained with the direction finder and from the rotating beacon agreed to within 5°. In some cases, however, due probably to the pitching and rolling of the ship, the accuracy of the direction finding bearing was inferior to that obtained from the rotating beacon.

As a result of the success of the experiments carried out with the Gosport station, a more permanent type of rotating loop beacon transmitter was installed at Orfordness and put into operation in June 1929. During the few months that this station has been working, a considerable number of reports have been received from various ships giving the results of observations made on transmissions from the beacon. These reports show that the inauguration of this beacon service has been very well received by the mercantile marine. With the ordinary type of ship's receiver adjusted for continuous wave reception, accurate wireless bearings are obtainable at distances of 50–100 miles. Ships fitted with a more elaborate receiver have reported good and consistent bearing observations up to ranges of 250 miles. At such long ranges, however, it is possible that the observed bearings may be subject to night errors in a manner similar to that observed in wireless direction finding under the same conditions.

From the similarity of performance of the two systems of direction-finding, it would be expected that the elimination of the horizontal components of the transmitting loop would be of advantage in eliminating or reducing the magnitude of night errors or effects observed when using the rotating beacon. A theoretical analysis of the case has shown this deduction to be justified, and experiments are now in progress towards the development of a rotating beacon transmitter with an aerial system of which only the vertical members are active in producing radiation of electromagnetic waves. If these experiments lead to successful results, it is probable that rotating beacons can be erected with a trustworthy working range of the order of 500 miles, supplying wireless bearings at any time or season with an accuracy which is adequate for both aerial and marine navigation.

Obituary

Sir William McCormick, G.B.E., F.R.S.

Few if any of the men interested in education since the days of the War have been better known to the vice-chancellors and treasurers of the universities of Great Britain than the late Sir William McCormick. None has had so complete a knowledge of their financial difficulties and of the disastrous effects on educational efficiency of their want of means, and no one has done more to help than he, by his sympathetic treatment of the problems placed before him, his wise advice based on his long experience, and his cordial appreciation of the value of the efforts made to fit the universities for their task, whether it be that of advancing knowledge, or of educating the students that fill their lecture rooms and laboratories. To all, his death on Mar. 22 means a very heavy loss.

McCormick was born on April 29, 1859, and educated at the Universities of Glasgow, Göttingen, and Marburg. For a short time he lectured on mathematics, but the study of the English language and literature soon attracted him, and he became, and continued to the end, a serious student of Chaucer.

After holding various lectureships on English at Glasgow, he was appointed professor of English in University College, Dundee, and then later, when the Carnegie Trust for the Universities of Scotland was established, he was chosen as its first secretary

But at this time new universities and university colleges were being established in England and Wales, and the question of State assistance to these became urgent A Treasury Committee, of which McCormick was a member, was set up to deal with this At a later date (1909) the Committee was transferred to the Education Office and he was made chairman In 1916 the Committee was again transferred to the Treasury as the University Grants Committee and Sir William remained chairman until his death The Committee was "to inquire into the Financial Needs of University Education in the United Kingdom, and to advise the Government as to the application of any grants that may be made by Parliament towards meeting them"

Figures perhaps give the clearest account of the magnitude of this work The recurrent grants made by Parliament are as follows 1913–14, £361,623, 1919–20, £889,000, 1930–31, £1,800,000 Between these last two periods, Oxford and Cambridge were added to the bodies receiving grants

The following words of a letter from Mr G H A Wilson, Master of Clare and member of Parliament for the University of Cambridge, of which he was Treasurer, give some indication of McCormick's method and of the value of his help

"By the death of Sir William McCormick the University of Cambridge has lost a sympathetic friend and a wise counsellor As head of the University Grants Committee of the Treasury, he always gave the greatest help and most valuable advice to the University in the many questions which were involved when the grant from the Treasury to the University was made

"The fears which had been expressed that the receipt of a Government grant might involve undue interference in the affairs of the University by a Government Department proved, under the wise and helpful guidance of Sir William McCormick, to be quite baseless Whilst prepared at all times to give advice when sought, he always maintained that the University should be left with the greatest possible freedom to manage its own affairs He was ever willing to meet suggestions as to the forms in which the accounts of the University might be modified to meet the special conditions existing at the University without departing from the necessity that those accounts should present a clear and accurate statement of University finance suitable for the needs of the Treasury"

To quote some words written since his death by one who, in earlier years, was his assistant in much of this work "His constant sympathy and wise counsel were always given with that peculiar charm that distinguished his personality The thing I enjoy saying of him most—and I say it with complete sincerity—is that if there was anything I did which was worthy, the credit and more than the credit was accorded to me, if I made mistakes (and there were plenty) he shouldered at once the entire blame That is the sort of thing that makes a junior worship a chief"

Meanwhile, important changes were in progress, the War had brought home to Great Britain the national importance of scientific research In May 1915 the Presidents of the Boards of Trade and of Education received a deputation from the Royal Society and other learned societies urging "Government assistance for scientific research for industrial purposes, the establishment of closer relations between manufacturers and scientific workers and teachers, and the establishment of a National Chemical Advisory Committee for these purposes" McCormick had been a member of a small Committee appointed by Mr Pease, President of the Board of Education, earlier in the year, which was responsible for the scheme ultimately adopted The Presidents replied to the deputation that the Government proposed to establish machinery with wider powers than those suggested by the memorialists, and a week later, when introducing the Board of Education estimates, Lord Gainford (then Mr Joseph Pease) announced the impending appointment of an Advisory Council for the supervision and encouragement of scientific research, particularly in relation to industry McCormick became chairman of the Council of eight members, only one of whom—Sir Richard Threlfall—is still with us Its first meeting took place on Aug 17, 1915 The order establishing the Council was signed by Mr Henderson, who on the change of Government had taken Mr Pease's place at the Board of Education

Even before the change, however, further discussions with the Government had taken place, and in these Sir William had borne a full share The Council had at first been instituted, for reasons of convenience, under the ægis of the Board of Education, but it had been decided—as one of the last acts of Mr Asquith when Prime Minister—that it should be established as a separate department under the Lord President of the Council, with its own offices This was announced in December 1916 by Lord Crewe, then Lord President

The first duty of the Advisory Council was to form a scheme or programme for its own guidance in recommending proposals for research, and for the guidance of the Committee of Council in allocating such State funds as were available, while to finance the work a grant of a million pounds was made, to be expended in accordance with these directions McCormick was present at the interview with the Chancellor at which the grant was made, and in his humorous way described the need and the discussions he had had with manufacturers when planning how best to meet that need "When people are starving," he said, "it is no use going to them with the Bible in one hand without a loaf of bread in the other."

To form a scheme was no easy task A Council of seven distinguished men of science, all of them fellows of the Royal Society, with a professor of English literature as chairman, set to organise under the pressure of a great war the application of science to industry The Council was fortunate

both in its chairman and its secretary, the reports of the last fourteen years give a record of its work, this is not the opportunity to attempt any detailed account Individual effort has been hitherto the basis of success of an English manufacturer, who has ever been an individualist It was clear at the start that grants to individual manufacturers would not accomplish the aims of the Council Co-operation in research was a new idea, at the same time, if it could be arranged, it was the one plan which seemed really hopeful, and thus research associations came into being, and in numerous cases have proved, by the work already done, the foresight of those to whom their existence is due, and the wisdom of the chairman who, for the past fourteen years, has guided the Council responsible for the supervision and approval of their work

How wise he was, with what skill and tact he guided that work, is known to all who were privileged to serve under him on the Council He has set it, it is true, on the right track, but the chairman himself, with his determination to go forward, along the path mapped out with so much thought and care, his realisation of the importance of its task, and his confidence that in the end success would come, will be greatly missed

McCormick was not a scientific man, but he has done more for science than many a professor in the subject, and it was a cause of no small pleasure to his friends—not least to the president and council of the Royal Society themselves—when some two years since the president was able to announce the recommendation of the Council, a recommendation unanimously approved, that it was desirable "in the interest of the advancement of Natural Knowledge" that he should be elected a fellow of the Royal Society under the special statute defining such elections Can we describe him better than the words of his own Chaucer

A knyght ther was and that a worthy man,
That fro the tyme that he first bigan
To riden out, he loved chivalrie,
Trouthe and honour, fredom and curteisie

He never yet no vileynye ne sayde,
In al his lyf, unto no maner wight
He was a verray parfit, gentil knyght

R T G

Prof W Robinson

Prof Wilfred Robinson, professor of botany at University College, Aberystwyth, died on Mar 7 after several months of ill-health He was born at Hull in 1884 and early became interested in botany, for his father, J F Robinson, a schoolmaster, was author of the "Flora of the East Riding of Yorkshire" He entered University College, Nottingham, and took his London B Sc (Hons) in botany His first post was science master at Penketh Friends' School, Warrington In 1912 he was awarded a research studentship at the Victoria University and became successively Platt scholar in botany, lecturer in botany, and assistant to the professor of cryptogamic botany, and then, in 1916, senior lecturer He was appointed to the chair at Aberystwyth in 1926

Robinson was a botanist of wide interests, keen in the field and careful in the laboratory During the War he worked on the microscopic cell wall characteristics of mechanical strains in timber, a matter of importance in the construction of aeroplane propellors His main interests for some time, however, were in plant pathology, and he visited the United States in 1924 on behalf of the Cotton Research Association to investigate the diseases of the cotton plant Several of his researches dealt with the physiology of fungi but, on going to Aberystwyth, he began to study the physiology of seaweeds and the life histories of some of the less common genera of the neighbourhood

With such wide interests and a natural flair for teaching, Robinson had an inspiring influence on his students and it is a great loss to cryptogamic botany that he was not spared long enough to enjoy the results of his industry and influence He took an active part in British Association matters and was recorder of Section K (Botany) until a few weeks ago

Dr Archibald Roderick Fee died on Feb 23 of septicæmia and broncho pneumonia, following the extraction of a tooth on Feb 15 His death deprives the subjects of experimental physiology and experimental biology of an active and devoted worker Dr Fee was only twenty four years of age at the time of his death, and his home was in West Burnaby, British Columbia He was a man of outstanding personality and possessed remarkable energy and great personal charm He came to England at the age of twenty with a degree from the University of British Columbia, and had already been engaged there in work for the Board of Fisheries which took him into uncharted waters of north western Canada He was a pupil in Great Britain of the late Prof E H Starling, who, like all his colleagues, had the highest opinion of Fee's ability and promise Dr Fee, at the time of his death, held a Beit Memorial Research Fellowship

We regret to announce the following deaths

Dr Henry Faulds, an authority on the finger print system of detecting criminals, and author of "Dactylography", on Mar 19, aged eighty six years

Prof Augustine Henry, formerly professor of forestry at University College, Dublin, on Mar 23, aged seventy two years

Dr J Y Mackay, principal and formerly professor of anatomy at University College, Dundee, on Mar 30, aged seventy years

Dr J W Robertson, C M G, first Commissioner of Agriculture and Dairying for the Dominion of Canada, and a pioneer of agricultural education in Canada, on Mar 19, aged seventy two years

Prof E G R Waters, professor of Romance languages in the University of Oxford, and an authority on British Micro Lepidoptera, on Mar 23, aged thirty-nine years

News and Views.

The impending resignation of Prof J Arthur Thomson from the chair of natural history in the University of Aberdeen severs the connexion with those occupants of the chair who taught both zoology and geology In 1908 the arrangement whereby the Department of Natural History was held to cover both zoology and geology came to an end when a separate lectureship in geology was instituted Prof J Arthur Thomson was appointed to the chair in 1899, and thus carried on the old arrangement for nine years The title of the original chair in Marischal College and University was that of civil and natural history, but when in 1860 the two Universities of King's College, Old Aberdeen, and Marischal College, Aberdeen, were united under the Universities (Scotland) Act, 1858, the chair became one of natural history in the University of Aberdeen The occupant of the chair of civil and natural history at the date of amalgamation was James Nicol, who had been appointed in 1853 Prof Nicol resigned and died in 1878, when J Cossar Ewart was appointed Prof Ewart resigned the chair in 1882 on his appointment to the chair of natural history in the University of Edinburgh He was succeeded by Henry Alleyne Nicholson, who held the chair until his death in 1899

Prof J Arthur Thomson, after graduating at the University of Edinburgh, proceeded to the Universities of Jena and Berlin, and was thereafter appointed lecturer in zoology and biology at the School of Medicine in Edinburgh, from which post he was appointed to the Aberdeen chair in 1899 The complete mastery of his subject, together with the lucidity and charm of his style, have earned for him a wide world reputation both as a lecturer and as a writer The Universities of Edinburgh and McGill conferred on him the honorary degree of LL D In 1915, he delivered the Gifford Lectures at St Andrews, and he has repeatedly been asked to lecture in the United States He was Terry lecturer at Yale University, and Morse lecturer at the Union Seminary, New York, while he is at present lecturing in the Zoology Department of the University of California at Berkeley and Los Angeles Particulars of the conditions on which the chair of natural history in the University of Aberdeen is held may be obtained from the Secretary of the University

Rumours concerning the future of the chair of organic chemistry at University College, London, have already been the subject of comment and protest in the correspondence columns of Nature It is not surprising that the suggestion to abolish the title of professor of organic chemistry should arouse suspicion that the future of organic chemistry itself at that college will thereby be jeopardised, and it is even less remarkable that those who have at heart the welfare of industries dependent on the progress of that branch of chemistry should be seriously perturbed by the further belief that a professor who is not an organic chemist may be appointed to fill the chair falling vacant by Prof R. Robinson's transfer to Oxford A letter recently addressed by the secretary of the Association of British Chemical Manufacturers to the Provost of University College expresses concern at the effect of such a policy on chemical industry, pointing out that intensive and continuous investigations in organic chemistry are essential for maintaining and improving our industrial position, and that any diminution therein of the facilities for instruction and research, which present experience shows to be still inadequate, may result in our once more becoming dependent on other countries for much that is vital to the health and prosperity of the nation

We have been informed by the Provost of University College, London, that henceforward the two chairs will be distinguished simply as the first and second chairs of chemistry, and that this must not be regarded as in any way affecting the position of organic chemistry in the College, it only secures to the College the freedom to make such recommendations as seem best in the interests of the College and of chemical studies as a whole It appears to us that the only reasons which would justify a change in the title of a position of such influence and standing would be inaccuracy of description of existing conditions and intention to vary them in the future, the former alternative is inapplicable, and it must therefore be concluded that the Provost's statement envisages the latter This can only mean that the position of organic chemistry at University College, London, is indeed affected, it may lose the status which is its due, it may lose that support and that momentum which can be fully given only by one of its own disciples, and its loss would be felt far beyond the limits of jurisdiction of the University of London It may happily be, however, that there is no intention of allowing organic chemistry to suffer any such disabilities, in which case it is difficult to understand why any change should ever have been proposed

The centenary of the death of Henry Hill Hickman was celebrated at a reception held at the Wellcome Historical Medical Museum on April 2, when Lord Dawson of Penn, president of the Royal Society of Medicine, gave an interesting address on this English pioneer in anæsthesia Hickman was born on Jan 27, 1800, near Ludlow in Shropshire, and qualified as a member of the Royal College of Surgeons twenty years later Like Edward Jenner, he was a general practitioner, and during the ten years of his professional life practised in the country towns of Ludlow, Shiffnal, and Tenbury At the outset of his career he performed a number of experiments on puppies, mice, kittens, and rabbits, which he rendered unconscious first through partial asphyxiation by the exclusion of air, then by inhalation of carbonic acid and later of nitrous oxide During the state of 'suspended animation', as he called it, so obtained, he performed incisions, applied ligatures, amputated ears and limbs, without the animals showing any signs of pain and with good surgical results In 1824 he published a pamphlet entitled "A Letter on Suspended Anima-

tion, Containing Experiments Showing that it may be safely employed during Operations on Animals with the View of ascertaining its Probable Utility in Surgical Operations on the Human Subject" The pamphlet was addressed to T A Knight, a fellow of the Royal Society, but no reference to it has been found in the *Transactions*, and contemporary evidence shows that the method was condemned as unpractical and dangerous Having failed to obtain recognition from his own countrymen, Hickman paid a visit in 1828 to France, where he addressed a memorial to Charles X requesting permission to develop his ideas in French medical and surgical schools The request was referred to the Académie de Médecine, where it appears to have met with general derision or indifference, although the famous surgeon Baron Larrey approved of the method and even offered himself for experiment Hickman returned to England a disappointed man, and died two years later at the early age of thirty years without having brought his work beyond the experimental stage

NOTHING more seems to have been heard of Hickman's work during the seventeen years following his death, although during this period inhalation of ether and, to a less extent, of nitrous oxide became an exciting fashionable amusement like the cocktail parties of to day It was not until after the publication of the work of Crawford Long, Horace Wells, and W T Morton in the United States on anæsthesia that the valuable achievements of Hickman began to receive attention It is gratifying to learn that Hickman's labours have at last received due recognition On the initiation of the Section of Anæsthetics of the Royal Society of Medicine, a fund, which has just been closed, was started for the restoration of Hickman's grave and tombstone in the cemetery of Bromfield Church and the erection of a memorial tablet, the balance being reserved for founding a medal for research and original work in connexion with anæsthesia The tablet, which is the work of Mr Eric Gill, was unveiled in Bromfield Church by Sir St Clair Thomson, a past president of the Royal Society of Medicine, on April 5 A souvenir volume, which was presented to those attending the reception at the Wellcome Historical Museum on April 2, contains an account of Hickman's work illustrated by contemporary portraits, facsimiles of his letters and other relics of him which are now on view in the Museum

IN the *Times* of April 5 there is an account of an experiment made to find out the time required to transmit the entire front page of a Californian newspaper from San Francisco to New York It was found that it could be done in three hours, and the inference is drawn that the feat is one of great significance We are told that the transmission was by radio waves of short wave length from a facsimile transmitter and that they were received in the laboratory of the General Electric Company at Schenectady The feasibility of doing this has been known for several years, but no evidence is quoted to prove that the given transmission is at present a commercial proposition The facsimile transmission of business correspondence by radio is already in established use on the eastern side of the Atlantic A good many problems will have to be solved, however, before anyone owning a radio receiving set can have his daily newspaper delivered to him every morning by merely attaching a recording apparatus to the set It is unfair to inventors to publish statements which lead the public to jump to the conclusion that it is only necessary to make slight improvements on known methods to increase their efficiency enormously Sometimes, also through the Press not understanding the object of an experiment, quite erroneous conclusions are drawn For example, when the Marchese Marconi sent a signal from his yacht at Genoa to operate a relay which by means of local power closed the switches controlling the electric lamps lighting the Sydney Exhibition 11,000 miles away, the conclusion was drawn that the radio transmission of power 'in bulk' was at last accomplished Although the experiment was noteworthy, it proved nothing as to the commercial feasibility of transmitting power by radio

THE last few years have witnessed a remarkable revival in polar exploration Few of the expeditions have been on a large scale, most of them being confined to one or more summer seasons in the Arctic or Antarctic, but they have generally been noted for intensive investigation of particular problems The time is thus opportune for the British Polar Exhibition, which is to be held in the Central Hall, Westminster, on July 2–15 next The exhibition will illustrate the deeds of British explorers from the sixteenth to the twentieth century One section will contain a loan collection of relics, historical documents, old charts, pictures, maps, paintings, flags, and ship models Another section will deal with modern polar work, including the research into whales and whaling now being conducted in Antarctic waters A third section will illustrate equipment, food, and appliances In this section various firms have promised help Two evening lectures will be given on south polar and north polar exploration respectively A polar booklet is being prepared for sale by Dr H R Mill Any profits that accrue from the exhibition will be distributed to societies or institutions engaged in geographical research A small committee is undertaking the arrangements, and Lieut Com L C Bernacchi, Carlton Chambers, 8 Regent Street, London, S W 1, is the organising director There is little doubt that the exhibition should evoke much interest and have considerable educational value in demonstrating the aims of polar exploration

A MOVEMENT for the encouragement of gliding in Great Britain has at last been initiated by the establishment of the British Gliding Association, with Air Vice-Marshal Sir Sefton Brancker as its first president Generous gifts, both of money and of apparatus, have been received from numerous well-wishers of this branch of aeronautics Meanwhile, clubs are being started in different parts of the country, and gliding looks as if it may become a popular and at the same time scientifically valuable sport We are, indeed,

gradually becoming air minded In Germany, where this movement, owing to restrictions on the use of the power unit in machines, is undoubtedly more advanced, the Government assists by subsidy on account of the aerodynamic information that has become available by this new activity The lecture on "Ten Years Soaring and Gliding in Germany", by Prof Walter Georgii, delivered before the Royal Aeronautical Society and recently noticed in these columns, has done much to provide the necessary precise technical details for successful development here, and has undoubtedly been largely responsible for the new impetus to the movement The British Gliding Association, with its offices at 44A Dover Street, London, W 1, has produced the first number of its new journal, which contains much valuable information on the subject

Partnership between science and industry formed the theme of Mr J Arthur Reavell's presidential address to the Institution of Chemical Engineers delivered on April 4 Scientific investigation, he said, has enabled the wool industry to turn out a product of higher finish and to utilise low grade wool and waste, in agriculture it has led to increased yields and improved quality, while in the steel industry the discovery of resistant alloys has led to great economies These are examples of the way in which science has aided industry, but there is still considerable delay in translating the findings of the laboratory into industrial practice To avoid this time lag, Mr Reavell pleaded for the representation of the scientific side of industry on boards of directors It is essential in modern industry, he said, that there should be scientific men on the boards of companies in whom their non scientific colleagues have sufficient confidence to enable decisions on technical questions to be taken with less delay Industry is not entirely to blame in this matter, for, in the past, scientific workers have largely neglected the financial side of industry This attitude must be changed, for science is now and must be increasingly in the future, a fundamental part of industry At the close of the address, the following medals were presented Moulton Medal, awarded for the best paper of the year of a mature character, to Mr H Hellings, Dr S Pexton, and Dr Chaplin, Junior Moulton Medal, awarded for the best paper by a graduate or student of the Institution presented to the graduates' and students' section, to Mr Harold Smith, Osborne Reynolds Medal, for meritorious service for the advancement of the Institution during the year, to Prof J W Hinchley, honorary secretary of the Institution It is of interest to note that the Moulton awards are made for the first time

The Final Report of the Departmental Committee on Ethyl Petrol has been published by H M Stationery Office (1s net) The report embodies the results of investigations extending over eighteen months on the prevalence of the occurrence of lead in normal urine, in the settled dust of the streets and in garages, on the quantities of lead found in the crank case oil and cylinder deposits of motor vehicles run on ethyl petrol, and on the possible danger to health arising from the spillage of ethyl petrol in confined spaces and from the exhaust gas of motor vehicles run on ethyl petrol The results of these investigations agree with those of the experiments carried out in the United States of America, and show that the use of ethyl petrol as a motor fuel would not increase the proportion of particulate lead in the air of the streets to such an extent as to constitute a risk to the health of the community The results of the investigations show also that the risk of injury to health from the spillage of ethyl petrol and from the absorption of lead tetraethyl through the skin is so small as to be negligible

The recent appointment by the Prime Minister of a committee to report on the desirability of establishing one or more national parks in Great Britain gives particular interest in an article in *Geography* for March in which Dr Vaughan Cornish takes a general survey of the coasts of Great Britain from this point of view He suggests first that the choice of a coast park should not lie in Scotland, on account of the short winter days, or in eastern England, with its low winter temperatures The south coast has obvious advantages in climate and accessibility but owing to the development of seaside resorts, it is scarcely possible to find a stretch of wild cliff scenery long enough to serve the purpose of a park His suggestions, finally, are that the most suitable sites are in the two peninsulas of Pembroke and Cornwall In Pembroke he points to the stretch of wild coast line between Strumble Head and Caldy Island, and in Cornwall to the cliff scenery between Cambeak and Trevose Head on the north coast and the granite cliffs of the Land's End In the chosen areas, a mild winter climate and relatively long days would enhance the value of the scenery and render the parks more valuable

The best method of eliminating the flue dust emitted from power station and factory chimneys is one which is being actively investigated by engineers at the present time When coal is burned upon a grate, the solids which pass into suspension are produced by the mechanical action of the draught raising the finer particles of the solid fuel With pulverised fuel, on the other hand, the fuel is burned when in the gases of the furnace In this case a greater percentage of solid matter reaches the chimney It was hoped that, as the dust is exceedingly fine, it would be carried great distances before it reached the ground Experience has proved that this is not the case In a paper read before the Association of Mining Electrical Engineers by J W Gibson, and published in their *Journal* for January and February 1930, a good introduction is given to chimney dust problems Several methods have been used in practice to eliminate the dust One of the earliest methods was to reduce the velocity of the flue gases so that the dust has time to fall out of suspension Another method is to use an electric precipitator, and for light dust concentrations this method is probably the best The method of spraying the smoke with water, technically known as washing, is being actively investigated at the present

time The quantity of water required is large, and if the coal contain sulphur the water gets acidulated and recirculation increases the acid concentration The water circuit, therefore, has to be designed so that it can resist corrosion In few cases would it be permissible to permit the effluent water to flow into a stream and the commercial solution of the problem of neutralising the acid is not easy Another promising method is to cause the effluent gases to rotate so that the dust is thrown out by centrifugal action Successful attempts have been made abroad to reduce the ash content of the fuel before it passes into the combustion chamber By combining several of these methods,successful results could be obtained

AT the present time the amount of nitrate obtained by the fixation of atmospheric nitrogen in the form of ammonia is equal to about half the total world consumption It is highly probable that artificial nitrate will replace natural nitrogen products In the *Brown Boveri Review* for December, a description is given of electrical machines which are particularly suitable for use in ammonia works and have been developed to meet the severe service conditions in this industry The production of ammonia by the high pressure process is divided into three distinct operations The first consists in isolating and purifying the gases nitrogen and hydrogen The second consists in combining those gases in the presence of a catalytic agent This has to be done at the most suitable temperature and pressure for the reaction In the third operation the ammonia is concentrated and combined with some agent to form the required commercial product Usual products are ammonium sulphate, calcium nitrate, and potassium nitrate In the first operation the nitrogen is usually obtained from liquid air by fractional distillation at very low temperatures Compressors and pumps are required for this process They are usually driven by 200 kilowatt motors contained in flame proof enclosures The production of hydrogen by electrolysis of water requires a very heavy current consumption, 25,000 kilowatts sometimes being used If only three phase current is available, it has to be converted into direct current This is usually done by rotating machinery Brown Boveri and Co , however, manufacture mercury arc rectifiers for this purpose having a capacity of 3000 kilowatts For the second process they also make a steam turbine driven turbo-blower which circulates gases at a pressure of 260 kgm per sq cm

WE have received from the director a number of the recent issues of the *Publications of the Hull Museum*, dealing, for the most part, with local antiquities Of these, No 163, "Hull Museum Treasures" is a reprint of articles by Mr T Sheppard, the director, which have appeared in the *Hull Daily Mail* during the past year Week by week some specially noteworthy object in the Museum has been exhibited in a case apart and has been figured and described in the local newspaper This is a method admirably calculated to stimulate local interest in the collections which may be commended to curators of other local museums Of more general interest to archæologists are two *Publications*, Nos 162 and 166 Of these, the latter contains the speech made by Sir Frederic G Kenyon in October last in declaring open the Mortimer Collection of Prehistoric Antiquities, while the former is the catalogue of the collection The Mortimer collection of prehistoric objects, from the barrows of East Yorkshire, was made by the two brothers R and J R Mortimer, corn merchants, of Driffield, in the last century Being first in the field, they were fortunate in being able to induce farm labourers to scour the country in search of relics Prizes were offered for the greatest quantity of implements found, one of these being a free trip to the Leeds Exhibition of 1868 Later, the brothers devoted themselves to opening up the barrows of East Yorkshire They brought together a remarkable collection of prehistoric, Roman, and Saxon antiquities which was described by J R Mortimer in his "Forty Years' Researches in British and Anglo Saxon Burial Mounds"

AFTER Mr J R Mortimer's death, Driffield failed to retain the collection as he had hoped it would, and finally it was purchased for Hull by Col G H Clarke at the very low price of £1000 The collection is now exhibited in the Old Art Gallery in the City Hall as "The Mortimer Collection, the Gift of Col Clarke" British archæologists owe a deep debt of gratitude to Col Clarke and to the trustees of the Mortimer estate for having kept this important and indeed unique collection in England, as it might well have gone to the United States at a much higher price The catalogue describes the collection, item by item, under the heading of each site the mound or grave in each case being stated It is well illustrated but it lacks a map of the area, and a plan of each site is much to be desired If the catalogue attains a second edition, as a work so valuable to archæologists deserves, these defects might be remedied

A COPY reached us recently of a paper on "A National Script for India", read in May last before the East India Association, London, by Dr A Latifi, Ambala, Punjab Dr Latifi makes it quite clear that, in view of the extreme complication of the Arabic and Devanagri scripts, Roman is virtually the only competitor in the field What he does not establish so unquestionably is that Roman must undergo considerable adaptation before it meets Indian requirements His main argument is that Roman script, in its unmodified form, leads to such inconvenient orthographies as ACHCHHĀ This, he suggests, would be rendered far better by a script which distinguished between the two A sounds, had a single symbol for the sound CHH, and used the Arabic *teshdid* as a mark of repetition In such a script, the word ACHCHHĀ would become ΛƐ̃A The emendation is certainly more concise, but is it really a simplification? The proposed new symbol is not an easy one to write, nor it is easy to see why Hindustani has more need for group sound symbols than have the European languages, which have so far managed to do very well without them If repetition of syllables is a feature peculiar to Hindustani, then there is a certain case for introducing the Arabic contraction, but to

differentiate the script any further seems only to be increasing the difficulties of communication between Indians and Europeans There is a quite natural temptation on the part of reformers to bestow on India the benefits of reforms which Europe in her linguistic conservatism rejects But it must be remembered that a familiar alphabet immensely facilitates the learning of a new language, and one may well question very seriously whether it is worth sacrificing this advantage for the sake of a slightly more perfect notational system

Referring to the letter on "Curling" by Mr W H Macaulay and General G E Smith in Nature of Mar 15, p 408, Mr Wm Taylor, of Messrs Taylor, Taylor, and Hobson, Ltd, Stoughton Street Works, Leicester, writes suggesting that 'borrow' is due to the difference of friction on the two sides of the cup, in one case the sum and in the other case the difference, of rotational and translatory motions being involved This, however, could not produce any sensible effect in the first 40 yards of the run of a stone, it would have an effect only quite close to the end Mr Taylor also suggests that the friction at the back edge of the cup cannot be greater than that at the front edge, the standard law of friction on ice, however, is that it decreases with increased pressure, the thawing due to pressure providing a lubricant The greater friction behind than in front is probably partly due to the rim of the cup being sharper inside than outside

Volume 21 of the Collected Researches of the National Physical Laboratory contains 448 pages devoted to 21 papers on magnetic and electrical subjects which have been written by the staff during the last five years and have in nearly all cases been published in the proceedings of scientific societies or in the scientific or technical periodicals during that period Seven of these deal with the design and accurate testing of standard inductances or of standard resistances which are to be as free as possible of induction Many of these problems arise in connexion with telephony, and radio waves and their propagation furnish the subject of nine other papers which deal with the polarisation and attenuation of the waves, the determination of the direction from which they come and the errors which might causes in the determination The wireless valve and the piezo electric quartz resonator each get a paper devoted to them, while problems of power distribution receive attention in papers on the losses in magnetic sheet material and in dielectrics respectively Terrestrial magnetism receives consideration in a paper on a coil method of determining the vertical component, and precision is imparted to the definition of the capacitance of a condenser by an investigation of the effect of its surroundings In short, the volume represents advances to which the staff may look back with considerable pride

The Huxley Memorial Lecture for 1930 of the Imperial College of Science and Technology, South Kensington, will be delivered by Prof Graham Wallas, on "Physical and Social Science", on Monday, May 5, at 5 30 p m

At the annual general meeting of the Physical Society, held on Mar 28, the following officers were elected for the year 1930–31 —*President* Prof A. S Eddington, *Hon Secretaries* Dr Ezer Griffiths and Dr Allan Ferguson, *Hon Foreign Secretary* Prof O W Richardson, *Hon Treasurer* Mr R S Whipple, *Hon Librarian* Mr J H Brinkworth

Brigadier General Sir Harold Hartley, fellow and tutor of Balliol College, Oxford, and Mr Allen Mawer, Provost of University College, London, have been elected members of the Athenæum Club under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

The following appointments in the Colonial Agricultural and Forestry Services have recently been made Mr C K Latham, Mr A S Richardson, and Mr A J Wakefield, district agricultural officers, to be senior agricultural officers, Tanganyika Territory, Mr R B Allnutt, to be district agricultural officer, Tanganyika Territory, Mr J R P Gent, deputy conservator of forests, Gold Coast, to be deputy conservator of forests, Nigeria

A memorial service for the late George Alexander Gibson, professor of mathematics in the University of Glasgow from 1909 until 1927, was held in the University Chapel on Friday, April 4 Prof Gibson, whom failing health compelled to retire from his academic duties after a long and strenuous period of service in the Royal Technical College and the University, was greatly respected as an able and conscientious teacher, while he also rendered important services as an administrator in earlier days in the work of reorganisation at the Technical College and later on as a member of the University Court

The Royal Geographical Society will celebrate its centenary in October this year According to the provisional programme recently issued, the celebrations will begin on Oct 21 with the opening of the Society's new lecture hall and other new buildings at Kensington Gore by his Majesty the King or one of the Royal Princes appointed by him Other events will include addresses on the history of the Society, on the history of exploration during the last century, and on certain other aspects of geography There will be a reception on Oct 22 and a centenary dinner on Oct 23 A detailed programme will be issued to fellows later

An important auction sale of botanical books and books of travel will take place on Monday and Tuesday next, April 14 and 15, when Messrs Christie, Manson, and Woods will offer at 8 King Street, St James's, S W 1, the library formed by Samuel Rudge, and his nephew, Edward Rudge, author of "Plantarum Guianæ Rariorum, 1805–7", containing many rare works

In the "Report on the Health of the Army for the Year 1928" (London H M Stationery Office Price, 5s net), recently issued, Lieut General Fawcus states that the year under review was the healthiest since the War, the admission ratio having fallen to

426 2 per 1000 of the strength, or 11 5 per 1000 below that of 1913 The invaliding and constantly sick ratios also show a reduction, although both are somewhat higher than in 1913 Among the men, the four chief causes of admission to hospital are venereal diseases (7213), malaria (6550), inflammation of tonsils (6110), and inflammation of areolar tissues (5465) The enteric fevers contributed only 42 cases, a remarkable record

VOL 1, consisting of six numbers, and No 1 of vol 2 of the *Technical Instrument Bulletin*, a journal devoted to optical and allied instruments as applied to industry and research, and issued in collaboration with the Emil Busch Optical Co , have now appeared Several of the articles have dealt with photography and photographic apparatus , among others may be mentioned contributions on choice of magnification in microscopy by Prof Hauser, on optical instruments for testing works materials by H Ehlert, on instantaneous photography of living micro organisms by A G Frewin, on the meaning of apperture by Dr Hans Schulz, on microscopical examination of glass by Dr L Springer, and on the magnifying spectacle by O Heinemann Copies of the journal will be sent on application to the editor, A G Frewin Diamond House, Hatton Garden, E C 1

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Two technical assistants, chemists, at the Royal Arsenal, Woolwich—The Chief Superintendent of Ordnance Factories, Royal Arsenal, Woolwich, S E 18 (April 14) An organiser of agricultural education for the Administrative County of West Suffolk—The Secretary of the West Suffolk Agricultural Committee, Shire Hall, Bury St Edmunds (April 19) A demonstrator in biology at Guy's Hospital Medical School—The Dean, Guy's Hospital Medical School, London Bridge, S E 1 (April 22) A research assistant in the mechanical engineering department of the University of Sheffield—The Registrar, The University, Sheffield (April 23) A temporary sanitary inspector for the Royal Borough of Kensington—The Medical Officer of Health, Town Hall, Kensington, W 8 (April 26) A lecturer in engineering at the Sunderland Technical College—The Chief Education Officer, 15 John Street, Sunderland (May 5) An assistant indexer for work in connexion with the forthcoming collective index at the Bureau of Chemical Abstracts—The Secretary, Bureau of Chemical Abstracts, Central House, Finsbury Square, E C 2 (May 9) Lecturers in pure mathematics and in geography at the L C C Shoreditch Technical Institute—The Education Officer (H2/1), The County Hall, Westminster Bridge, S E 1 (May 10) A lecturer in the Department of Phonetics at the School of Oriental Studies—The Director, School of Oriental Studies, Finsbury Circus, E C 2 (May 15) Part time lecturers in Siamese and Tibetan, respectively, at the School of Oriental Studies—The Director, School of Oriental Studies, Finsbury Circus, E C 1 (June 14) A science master, chief subject chemistry, at Bishop's Stortford College—The Head Master, Bishop's Stortford College, Herts A public analyst for the purposes of the Food and Drugs (Adulteration) Act, 1928, for the county of Southampton—The Clerk of the County Council, The Castle, Winchester

Our Astronomical Column

A New Trojan Minor Planet —*Circular* 294 of the Astronomisches Recheninstitut contains an announcement by Dr G Stracke that he has discovered a seventh Trojan planet It was found by K Reinmuth, assistant at Königstuhl Observatory, on Jan 27, and observed by him again on Feb 19 and 24 , Dr Stracke deduced the orbit from these three places,and finds the mean daily motion to be 297 852″, almost exactly that of Jupiter Both i and ϕ are moderate, being 3° 9′ and 8° 42′ respectively, so the oscillations from the equilateral position will not be so large as in some cases It makes a fifth member of the group of Trojans the longitude of which is 60° greater than that of Jupiter, while there are only two on the other side of Jupiter

The New Planet.—A circular from the Lowell Observatory, dated Mar 13, combined with several numbers of the *Daily Science News Bulletin*, issued by Science Service of Washington, D C , give details of the discovery The Lawrence Lowell photographic telescope was devoted to the search for the body, the existence of which was predicted by the late Prof Percival Lovell The work was placed in the hands of Mr Clyde W Tombaugh, a young assistant who joined the Observatory staff in January 1929 He systematically surveyed the ecliptic zone, and had nearly half completed the circle when on Jan 21 last he detected the new orb in the vicinity of Delta Geminorum The discovery was confirmed by plates taken on Jan 23 and Jan 29, and since Feb 19 the planet has been regularly followed Examination in the 24 inch refractor failed to show a definite disc , comparison of the visual with the photographic magnitudes shows that its light is yellower than that of Uranus or Neptune

Circular No 7D of the Société Astronomique de France reports that M F Baldet observed the planet visually with the 33 inch refractor at Meudon on Mar 20, 27, and 28 , he satisfied himself that the angular diameter did not exceed 0 2″, which corresponds to 4000 miles at a distance of 45 units He makes the erroneous statement that a body of diameter 1500 kilometres and albedo 0 15 would appear of magnitude 15 at distance 45 This error of taking the light as varying as the inverse square of the distance, instead of the inverse fourth power, since the distances from both sun and earth have to be considered, has been common

The *Illustrated London News* of April 5 contains excellent reproductions of five photographs of the planet, taken at Flagstaff, Yerkes, Neubabelsberg, Merate (Milan), and Oxford (Radcliffe) The Flagstaff photograph is undated, but was probably taken early on Mar 2 (U T) Measures on the photograph give the following position for the planet for the equinox of 1930 0 R A 7^h 16^m 13^s 72, N Decl 22° 5′ 18 3″ It was then 17^s east of δ Geminorum, which it passed about Mar 8 It is now again approaching the star, but owing to its northward motion it will clear it on the north side on its return journey The inclination of its orbit to the ecliptic appears to be about 14°, which helps to explain why it was not picked up sooner, as twenty years ago it was several degrees south of the ecliptic

Research Items.

Gipsy Exorcism—In Pt 3, Vol 8 of the *Journal of the Gypsy lore Society*, Ser 3, Mr Engelbert Wittich describes some of the fraudulent tricks practised by German gipsies, and includes among them two forms of exorcism—*digno dorgaben* ('little exorcism') and *baro dorgaben* ('big exorcism') By 'little exorcism' is meant the curing of illness, but 'big exorcism' is the expulsion or exorcism of an evil spirit which is bringing misfortune to the house The practice of 'little exorcism' for illness is usually left to a female gipsy The patient is given three chestnuts, of which one has previously been bored with a red hot needle These 'magic' chestnuts are said to have been obtained from a 'holy tree' in India, and must be worn by the patient next the skin for three days and three nights If at the end of that time they are split open in the presence of the gipsy, and one of them is found to have a black stain in the middle, this is a bad sign portending death This fate can only be averted by the payment of a sum of money which the gipsy spends on obtaining magic herbs and potions 'Big exorcism' comes into operation on the indication of the presence of an evil spirit by a snake's skin, the heart of a bat still fresh, or a hedgehog's foot with the bones arranged to resemble a child's hand, being found when the householder is digging in his garden The evil spirit must be made *gamlo* (kindly) Holy water must be obtained at considerable expense from a holy spring in India, known only to a limited number of the gipsy's people The whole place is then sprinkled with the water, and digging is undertaken in the garden to see if the spirit is appeased If, as is usual, another sign of misfortune appears, the *baro rom* or 'big man', that is, the wizard, or the *baro tschuwl*, the 'great woman' or witch, is called in He comes with great solemnity, accompanied by some sign, the cattle become restless, spirit candles burn with a blue flame in the garden, etc After an incantation—"Bind the straw, hang the straw, give the horses water"—the gipsy finds in one of a plate of hard boiled eggs over which he has repeated his incantation three times a curiously coiled horse hair, a presage of evil The ancestors of the victim have incurred the wrath of Heaven by a serious crime A large sum of money is buried in the garden with three hens' heads This ultimately is found to have been changed into a root curiously formed, which must be carefully tended for years until prosperity returns

Rapid Changes in Mammals caused by Climate—It is seldom that the process of change of characters comes under observation, but the history of the acclimatisation of four different species of marsupials seems to offer a case in point About 1870, the late Sir George Gray introduced several species of wallabies from Australia to Kawau Island, near Auckland, New Zealand A. S La Souef now records that the intervening sixty years have impressed themselves in quite a definite way upon the fur of the wallabies (*Australian Zoologist*, vol 6, p 111, 1930) In three species the same change is noted, that the fur is softer, more silky, and longer, and that while the colouring is darker the markings are more pronounced In only one of four species of wallabies examined was there no alteration from the normal Australian type The likelihood that the change is a result of environment is strengthened by the similarity of change shown by opossums which also have been introduced into New Zealand In these also the fur is found to be longer, more silky, and less dense, and the alteration in character is so marked that, according to the author, one has no difficulty in distinguishing New Zealand opossum pelts from among thousands that may be offered in a sale room

Food-storing by Californian Woodpeckers—The well-known studies of the acorn storing habit of the California woodpecker (*Balanosphyra formicivora*), to which Prof W E Ritter has devoted many years, have been pushed to a new stage by the author (*Quart Rev Biol*, vol 4, p 453, 1929) in his attempt to estimate the functional or evolutionary value of the habit to the birds themselves By various means he has tried to test the survival value of acorn storing, and his strong conclusion is that, although the habit shows sharp limitations to its adaptiveness, it nevertheless is distinctly to the advantage of the California woodpecker For example, a rough census of the numbers of this species in various districts shows that it exceeds its nearest competitors, the flicker and the Lewis woodpecker, in a proportion varying from three to one to five to one These others do not store food, and Ritter argues that food storing, by making the California woodpecker less dependent on local environmental conditions during severe weather, has reduced the rate of mortality and increased the numbers of birds Close study of the storing habit shows that it is no general activity but conforms minutely to varying external conditions, in fitting storage holes for acorns of different sizes, in selecting nuts of convenient size for handling, and in several other respects, all of which are intrinsic evidences of the adaptiveness of the activities On the other hand, maladaptations are manifest in the occasional storing of objects which cannot be used as food, in the storing of food where it cannot be recovered, and in the making of storing holes which are never used at all

Nematode Infection of a Young Dolphin—In an interesting address to the Quekett Microscopical Club, published in the Club's journal of December last, on the life histories of some nematodes, Dr H A Baylis refers to the group of related genera and species of nematode worms which occur only in whales, porpoises, and dolphins and are usually found in the bronchi, the air containing cavities in the head, or in the blood vessels Each species of worm seems to be strictly confined to one or two kinds of host, and in some species of Cetacea practically every individual appears to be infected Dr Baylis records a heavy infection of adult worms in a dolphin so young that its stomach was still full of its mother's milk, and points out that if the larvæ of the worm were discharged into the sea they would be unlikely to reach the proper host again He therefore suggests that pre natal infestation occurs, the worms being regularly handed on from mother to offspring As the worms are viviparous this would be possible, for larvæ would probably always be available so long as adult worms were present

Nitrogen Fixation by Bacteria—The question as to whether or not the nodule bacteria of leguminous plants can fix atmospheric nitrogen independently of their host has always been a vexed one, the results previously obtained by a large number of workers being decidedly conflicting It is, therefore, of particular interest that three papers have recently appeared on this subject within a few weeks of each other by independent workers, all of which are unanimous in their conclusion that no fixation of nitrogen occurs apart from the host plant F E

Allison (*Jour Agr Res*, **39**, p 893), working with 31 strains of legume nodule bacteria, grown in a large number of media, under a variety of conditions, has obtained consistently negative results His conclusions were based on nearly a thousand analyses determined by the Kjeldahl method E W Hopkins (*Soil Science*, **28**, p 433) gives a useful tabulated summary of all previous investigations, results and working conditions He also obtained no evidence of nitrogen fixation from any of the five hundred analyses carried out with the Davisson Parsons method M E Löhnis (*Soil Science*, **29**, p 37) has also obtained a negative answer to the question, employing in some experiments the Gunning Arnold and in others the ter Meulen micro method for the nitrogen determinations It would seem particularly convincing that all three workers have secured similar results although each used entirely different methods

Ionised Layers in the Upper Atmosphere—A report on part of the work of the Peterborough Radio Research Station of the Department of Scientific and Industrial Research has been published by Prof E V Appleton in the March number of the *Proceedings of the Royal Society* In this paper, attention has been mainly directed to variations in the equivalent height of the layers of ions responsible for the reflection of the waves used in wireless transmission, as studied by the interference fringes formed at Peterborough between waves coming directly from Teddington, Bournemouth, or Birmingham, and those coming by way of the upper air It seems now to be highly probable that the reflecting stratum is really multiple, the secondary maxima and minima which sometimes accompany and occasionally replace completely the main fringes have properties which are difficult to reconcile with the view that they always arise through multiple reflection between a single layer and the ground, but are readily accounted for in terms of a second layer at a height of approximately twice that of the main 100 km layer The properties of at least the 100 km layer are, however, in common with most atmospheric phenomena, somewhat erratic, for occasionally it will remain at about the same height during the observations, instead of rising as it usually does to some 125 km at the hour before sunrise The theory that a solar radiation is responsible for the production of the ions fits in well with most of the observations, but much still remains to be found out about the details of its action, and the nature of the ions Two further papers are to appear, on simultaneous reception at different stations, and the results obtained with waves shorter than those made use of for the work described in the present paper

Electric Power Stations in Japan—In a paper read at the World Power Conference in Japan, an abstract of which appeared in *Engineering* of Jan 31, S Fukumaka discussed the joint operation of steam and hydroelectric power stations in Japan Since 1922 electricity supply has increased very rapidly and increasing use has been made of water power The steam stations are now mainly used to supplement the water power plants at times when the load is very heavy This reduces the cost of the energy supplied to a minimum and conserves fuel Fukumaka divides the power from hydraulic plants into two parts The first is the power capacity based on the minimum flow throughout the year, and this power, which he calls primary, is continually utilised The second part consists of the excess power that can be generated during the rainy season This part can be considered primary if it can be supplemented when necessary by steam plant In order to obtain the best results, the economical problems need modification for each case The total electrical supply in Japan now exceeds three million kilowatts The peak of the seasonable load, however, occurs in winter when the water power available is least The steam plant which has to be installed to meet this shortage must be cheap It must be capable of meeting large fluctuations and the time necessary for starting it must be small In addition, the operating staff must be small and the stand by charges a minimum These requirements are influencing the design of all the new stations, with the result that the use of pulverised fuel is becoming general

Extinction of Methane Flames by Water Vapour—Some interesting experiments on the effect of water vapour on the limits of inflammability of methane in air, which supplement those made in 1926 with carbon dioxide, nitrogen, argon, and helium, are described in the February number of the *Journal of the Chemical Society* by Coward and Gleadall The extinctive action of five of the six diluent gases runs in the order of their molecular heat capacities Helium has an exceptionally high extinctive effect, ascribed to its abnormally high thermal conductivity Other factors have very little influence carbon tetrachloride, although it undergoes extensive reaction in the flame of a methane-air mixture, falls into line with the other diluent gases

Passive Copper—The results of some measurements of the adhesion of 'passive' copper are given by M Nottage in a paper in the March number of the *Proceedings of the Royal Society* The copper was made passive by first boiling in absolute alcohol, and then plunging whilst still hot into dilute nitric acid Experiments with ordinary copper and steel showed that passive copper adhered very strongly to a similar surface, the value of the adhesion with palmitic acid lubrication being 21,000 gm per sq cm, whereas ordinary copper has an adhesion of 14,200 gm per sq cm against itself The passive copper had a uniform reddish tinge, quite unlike the patchy appearance of the usual tarnished surface, and was presumed to be coated with a very thin layer of cuprous oxide, which possessed considerable permanency, persisting for example on rubbing with fine magnesia powder on silk, and on exposure to impure damp air The results of the adhesion determinations are taken to indicate that the surface film produces a decided increase in the intensity of the attraction field

Oxidation of Acetaldehyde—Although it is known that, in the oxidation of benzaldehyde by oxygen, peroxides are formed, there was no information as to the course of the oxidation of acetaldehyde, Liebig in 1835 having observed that it absorbs oxygen at the ordinary temperature, giving, according to him, acetic acid In the February number of the *Journal of the Chemical Society*, Bowen and Tietz have shown that a peroxide of acetaldehyde is quantitatively formed, that it is a moderately stable substance, and that it is produced thermally as well as photochemically when liquid acetaldehyde is shaken with oxygen There are two possible peroxides, namely, peracetic acid, CH_3 CO O OH and diacetyl peroxide, CH_3 CO O O CO CH_3, both of which have been prepared in other ways The photochemical reaction is essentially the same throughout the ultra violet absorption band of acetaldehyde, and the rate is proportional to the square root of the light intensity The formation of diacetyl peroxide occurs in the gaseous, liquid or dissolved states, but it is probably produced by secondary reaction of peracetic acid, which is assumed to be the first product in a chain reaction

The Viscosity of Liquids.

Among the properties of liquids the viscosity is probably the one the investigation of which has suffered most from lack of any accepted theory, however crude and approximate, to guide it A great body of more or less careful observations exist, but it has furnished remarkably little information as to the nature of the liquid state The new technique of X rays, the Raman effect, and the depolarisation of light may do much to elucidate the structure of liquids, but the older and grosser property of viscosity must be at least as pertinent Recently, a letter of mine published in Nature of Mar 1 upon the subject of liquid viscosity called forth a number of letters, and seemed to make it advisable to say a little more of a theory which, little elaborated as it is, offers a picture which may prove helpful The conception of a transitory and fluctuating 'crystallisation' of a liquid seems to fit in with other observations I am far from being satisfied with the theory as it stands my hopes go no further than that the facts cited in my present letter may suggest to some that there is a germ of truth in the point of view put forward At any rate, I intend to make some measurements myself of the temperature coefficient of liquid viscosity, in the hope that they may throw some light on the old problem as to the force exerted on a single molecule by the molecules in its immediate neighbourhood, within the Lorentz sphere

---

The letter of Prof Andrade in Nature of Mar 1 raises the interesting question as to the reason for the decrease in viscosity of a liquid with rise of temperature This seems to be closely connected with the similar decrease in the frictional resistance due to the motion of solid bodies through liquids I have been lately carrying out some experiments on this latter subject as follows

Two rings of thin sheet brass were cut off a drawn brass telescope tube about 2 inches in diameter One ring was 1 inch deep and the other 0 25 inch deep These rings could be suspended one at a time by four very fine wires with their axes vertical from the bottom of a cylindric inertia mass, which last was hung by a single steel torsion wire The arrangement was such that the thin rings could be set oscillating in a liquid successively, with the rings totally immersed in it, but the inertia mass not immersed The object of using rings of different depths was to eliminate any energy loss due to wave or eddy current making due to the fine suspending wires or edges of the rings The measurement consisted in displacing the suspended mass through a certain angle, say 120°, and then noting the time required for this angle of maximum displacement to be reduced to 60° for the two rings This gives by difference a measure of the frictional resistance per unit of surface If the frictional resistance were exactly proportional to the velocity then the differential equation for the motion would be

$$I\frac{d^2\theta}{dt^2}+R\frac{d\theta}{dt}+C\theta=0,$$

where I is the moment of inertia of the oscillating mass and C the coefficient of restoration and θ the angle of displacement If t' is the time required to decrease the initial amplitude of displacement to half its value, then it is easy to show that $R=1\ 38I/t'$

On making the measurements in tap water at various temperatures the following results were found

15° C	$R=19\ 75$	60° C	$R'=10\ 1$
30°	15 2	70°	10 7
50°	12 1	80°	10 6

It is seen that a rise of temperature of the water from 15° C to 80° C reduces the frictional coefficient R to about half its value

This method is sufficiently sensitive to show the difference between fresh water and sea water at the same temperature

If we ask the reasons for it the following suggest themselves The cause of friction between a solid and a liquid may be regarded as of the same nature as the reason for the coherence of molecules together to form either a solid or a liquid In view of the assumed electric structure of atoms, this coherence must be regarded as due to electrical attractions between atoms or molecules Rise of temperature ionises or dissociates molecules into ions or atoms and promotes mobility of these with respect to the mass of the liquid Hence follows a reduction of the force required to shear a liquid surface along a solid

Experiments made with paraffin oil (Royal Daylight) showed that, although this liquid seems more limpid than water, the coefficient of frictional resistance with the brass rings was considerably greater The oil is, however, a good dielectric and therefore not ionised so much as tap water at the same temperature The practical result is that if the sea had an average temperature of 80° C instead of about 15° C, ships would require less power to drive them through the water than at present I am continuing these experiments as time permits

Ambrose Fleming

Manor Road, Sidmouth,
Mar 1

I have read with great interest Prof Andrade's letter in Nature of Mar 1, dealing with the temperature variation of the viscosity of liquids The theoretical side of this question has admittedly been curiously neglected with perhaps one or two exceptions, of which one of the earliest was Maxwell Considering, however, how generally the idea of a time of relaxation has entered into modern molecular theory, particularly in relation to liquids, it is more than probable that Maxwell's original conception of the viscosity process will receive an elaborated physical interpretation

In view of this fact I should like to mention a formula connecting the viscosity and temperature in liquids which I have had occasion to examine in a paper which has been communicated elsewhere, and which may be built up from Maxwell's fundamental definition of liquid viscosity This formula

$$\eta=\frac{Ae^{\beta T}}{T-b}$$

holds for a number of liquids over a wide temperature range, which liquids include both normal and associating liquids The accompanying table shows two examples The formula has admittedly three constants but is similar to that of Prof Andrade in that it contains an exponential function From general molecular theory and in view of the direct relation between viscosity and vapour pressure, it is probable that an exponential form of equation

for viscosity and temperature will prove to be the most satisfactory In this connexion a comparison of the derivations of J S Dunn's equation (*Trans*

Stockland Green,
Erdington, Birmingham

A SATISFACTORY explanation of the decrease of liquid viscosity with temperature has long been required, and Prof Andrade's theoretical treatment of the subject will be awaited with interest His simple formula connecting viscosity and temperature appears to give good agreement for certain liquids, but I should like to point out that it does not give such good agreement when applied to measurements on some mineral oils, as does a formula due to Slotte The measurements were taken several years ago and in attempting to find an empirical relationship between the viscosity and the temperature, I obtained, quite independently, a formula which was identical

with that due to Slotte and adopted by Thorpe and Rodger as best representing their experimental results This formula is usually written in the form

$$\eta = \frac{c}{t + a}n$$

where η is the viscosity, t the temperature in °C, and C, a and n constants depending on the liquid used The constants A and b in Prof Andrade's formula (NATURE, Mar 1, p 309) have been calculated for a somewhat viscous oil from the viscosity values at 35° C and 80° C, and the agreement between the observed results and those calculated from the two formulæ shown in the accompanying table

One naturally expects to be able to obtain closer agreement between observed and calculated results with a formula containing three constants than with one containing two, but in this connexion a further interesting fact was observed It was found that the value of C obtained from eight oils of widely varying viscosities could be expressed with considerable accuracy by the formula

$$C = ad^n$$

where a and d are constants which are independent of the nature of the oil and the approximate values of which were $1\,5 \times 10^{3}$ and 400 respectively Thus Slotte's formula also becomes one in which there are only two constants the values of which are dependent on the nature of the liquid On examining the values of C and n obtained for other liquids it was found that, with the exception of the alcohols, they were connected by a similar relationship, the values of a and d differing but slightly from those obtained for the mineral oils This empirical relationship was not published, and it was thought that the results might be of some interest when considering the theoretical aspects of the problem

IN a recent issue of NATURE (Mar 1, p 309) Prof Andrade publishes the following formula, $\eta = Ae^{b/T}$, for the coefficient of viscosity of liquids as a function of the temperature T, which he shows to be in excellent agreement with the experimental data Now I wish to point out that a practically equivalent formula, namely, $\eta = CTe^{U/kT}$, was given by me more than four years ago in a paper on the heat motion of solid and liquid bodies (*Zeit f Phys*, **35**, p 664 667, 1926) Since this has obviously remained unnoticed, it may be well to state briefly the fundamental conception on the heat motion of liquids upon which the above formula is based

The 'crawling' of the particles of the liquid is considered as a combination of oscillations about a (temporary) position of equilibrium and of a jerky displacement of this position from time to time The average number of oscillations performed about the same equilibrium position is equal to $e^{U/kT}$, where u is the energy required to tear the particle out of it An elementary displacement of the equilibrium position is consequently achieved in a time $\tau = \tau_0 e^{U/kT}$, τ_0 being the period of the oscillations, which corresponds to a 'crawling' velocity $v = \frac{\delta}{\tau} = \frac{\delta}{\tau_0}e^{-U/kT}$, where δ, the average range of this displacement, is of the order of the mean distance between neighbouring particles, and to a diffusion coefficient $D = \frac{1}{3}\delta v = \frac{\delta^2}{3\tau_0}e^{-U/kT}$ Now the latter is connected with the friction coefficient f(= ratio of force to the mean velocity which is due to it) by Einstein's formula $Df = kT$ If, on the other hand, we regard the particle as a small sphere of radius $a \cong \delta$ then we have by Stokes's formula $f = 6\pi a\eta$ Hence $\eta = \frac{\tau_0 kT}{2\pi a\delta^2}e^{U/kT}$ which is the above formula with $C = \frac{\tau_0 k}{2\pi a\delta^2}$,

Putting here $\tau_0 \cong 10^{-13}$ sec and $a \cong \delta \cong 10^{-8}$ cm one gets for C or Andrade's coefficient $A = CT$ values of the correct order of magnitude.

J. Frenkel.

Physico Technical Röntgen Institute,
Leningrad, Mar. 8.

I am naturally gratified at the interest which my brief letter on liquid viscosity, published in Nature of Mar. 1, seems to have aroused. In view of the correspondence which has ensued I should like first to indicate briefly the theoretical considerations, mentioned in passing in my former letter, which lead me to the formula $\eta = Ae^{b/T}$, secondly, to refer to the general directions in which I look for experimental confirmation, and thirdly, to discuss some of the points raised by the correspondence.

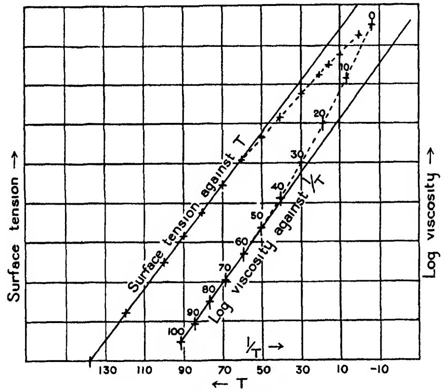

Fig. 1.

The method by which I arrive at the formula is by taking two layers of molecules, parallel to the direction of motion of the liquid and considering the transfer of momentum between them. In the case of a gas, Maxwell showed how the viscosity can be derived by considering this momentum as being communicated by molecules transferring themselves bodily through a distance large compared to their own sizes, from one layer to the other. But both the non-fulfilment of the conditions postulated in Maxwell's treatment, and the fact that while gas viscosity goes up with temperature liquid viscosity goes down, show that some radically different picture is needed for liquids. I suppose that momentum is transferred from layer to layer by a temporary union of molecules in contiguous layers, the duration of this union not exceeding the very brief time required for the molecules to acquire a common velocity of translation. The union takes place under the action of the residual field of the molecules, which suffices to bind them permanently in the solid state, but is overcome by the energy of motion in the liquid state. General considerations suffice to show that the greater the temperature agitation the smaller the probability that the residual field of fixed average strength will result in temporary union for a given molecule. The viscosity of a liquid, therefore, decreases with rise in temperature until finally the energy of motion overcomes the molecular field and the liquid boils. The general picture is one of the liquid 'crystallising' temporarily in minute patches; at the temperature of solidification the crystallisation becomes general and permanent, at the boiling point it must be very small.

To obtain the quantitative law more precise assumptions are necessary. We can suppose that the temporary combination represents the position of minimum potential energy of the molecule with respect to the local field. Just as in Langevin's theory of magnetism the tendency of the molecules to set, with respect to an *external* field, in the position of minimum potential energy, with axes parallel to the field, is opposed by the thermal agitation, so here too the tendency of two molecules to combine is opposed by the thermal agitation. The simplest application of Boltzmann's formula leads to the viscosity formula given in my former letter. In this formula the constant b is, of course, of the form $-E/k$, where E is the energy, numerically negative, of juxtaposition, k the Boltzmann constant. The constant A contains as factors $M^{2/3}\rho^{-1/3}$, where M is the molecular weight, ρ the density. The formula virtually assumes that the number of impacts is independent of the temperature, the effect of the increased velocity being opposed by certain factors, such as the expansion. It is probable that A depends slightly on the temperature, and I am now trying to elaborate this point, but comparison with the recorded data shows that A may be taken as a constant to a first approximation.

It is my belief that the constant b, expressing in some way the strength of the intermolecular field, will prove of great importance for the theory of liquids, and will take its place alongside the surface tension. The constant b can be accurately determined from the variation of viscosity with temperature, the constant A less so, it being very insensitive, like the constant A in O. W. Richardson's thermionic formula.

One way in which to check the reasonableness of the hypothesis on which the theory is based is to calculate the number of momentary combinations which it requires to give the observed viscosity. Just above the

melting point I suppose that practically every collision leads to a sharing of momentum, so that the number obtained should be of the order of the total number of collisions In the case of mercury this number comes out to be 3 7 × 10[12] per sec , which is reasonable, being of the same order as the vibration frequency of the solid I have also obtained a rough value for the internal pressures of one or two organic liquids, which come out to be of the right order, but the assumptions made in this case are of a tentative nature, and I am now devoting further attention to this problem

I distinguish between true association, as occurring in liquids ordinarily called associated, and the brief union needed for the sharing of momentum which I postulate for all liquids True association, in which molecules are bound together in clusters of two or more for a time large compared to the intervals between collisions, leads, with the mechanism postulated, to an increase of viscosity The application of the formula to many associated liquids leads to some very interesting results It is found to hold accurately at higher temperatures, but as the temperature falls the actual viscosity becomes increasingly greater, compared to that predicted by the formula This I take to mean that at the higher temperatures the liquids are either not associated at all, or else that such association as may exist is of a stable kind, unaffected by the temperature In the case of water the formula $\eta = Ae^{b/T}$ expresses the viscosity within 0 5 per cent from 100° to 60°, when the deviation begins to set in and rapidly increases It is striking that the surface tension of water is a linear function of the absolute temperature above 60°, but that below 60° the deviation from linearity rapidly increases, as shown by Fig 1, in which surface tension plotted against T, and the logarithm of viscosity plotted against $1/T$, are exhibited in the same diagram As an inverse temperature scale would make it troublesome to trace the point at which the viscosity law changes, the actual temperature values of the different points are indicated on the curve itself Water and many other associating liquids can be fitted by the formula $\eta = A'e^{b/T-\theta}$ as an approximation, the formula having no detailed theoretical basis, but being derived by an obvious analogy from other branches of physics For water the fit is within about 1 per cent throughout the range It seems more reasonable, however, to use a formula of the type $\eta = A(1 + \alpha e^{-\beta T})e^{b/T}$, the term $1 + \alpha e^{-\beta T}$ expressing the decrease of association with temperature This formula, it is true, has four constants, but four constants are commonly used in empirical formulæ designed to fit water[1] It gives the viscosity over the range $T = 263$ 7 (supercooling of 9° C) to $T = 363$ within 0 25 per cent (the viscosity at 100° seems experimentally doubtful) The variations in the viscosity of water, as measured by different observers of high repute, markedly exceed this at many temperatures There is no indication of a systematic deviation For fitting the formula I have taken the mean of the results of Hosking, and of Bingham and White, as given in Landolt Bornstein, 1923 edition, for which the greatest variation at any one temperature is 0 9 per cent, while at most temperatures the agreement is good For supercooled water the values of White and Twining, quoted in Landolt Bornstein, are taken

The accompanying table exhibits the fit

If b measures the strength of the molecular field, as defined by the conditions specified, it should be connected on one hand with the boiling point, and on the other hand with the dielectric polarisation due to deformation of the molecule In all homologous series for which measurements are accessible to me, b increases regularly with the boiling point and with the polarisation This is an aspect of the subject at which I am now working with some promise of result Among other results obtained by considering the variation of b throughout homologous series, I may mention that plotted against numbers of carbon atoms for the fatty acids, b lies on one curve for the odd numbers of carbons, and another for the even numbers The data are very scanty, but this conclusion seems justified, and extends to the liquid state conclusions based on the behaviour of the solid state to X rays

The variation of viscosity with pressure is another part of the subject which is yielding promising results The general nature of the increase is clearly represented by the theory, log η being a linear function of P as a first approximation, but even in cases such as water something of a more quantitative nature has already been obtained The viscosity of solutions is another field to which the general formula is being applied

One of the greatest troubles which I have met with in trying to check the theory is the lack of precise data Organic chemists tell me that it is doubtful, for example, if the fatty acids used for the recorded determinations were pure Again, the variations between the results obtained by different observers with certain of the most ordinary substances, for example, ethyl ether or mercury, are very large for ether they amount to as much as 9 per cent in the neighbourhood of 20° C , and for mercury to 3 per cent at temperatures above 140° C (see Erk, "Unsere Kenntnis der Zähigkeit von Quecksilber," *Zeitschrift für Physik*, 47, 886 , 1928) The range of measurements

In the experimental values for 95° and 100° Hosking's values, which are markedly higher than those of other observers, are omitted The values given are averages for Slotte, Thorpe and Rodger, and Bingham and White Accurate determinations in the neighbourhood of the boiling point are badly needed

[1] The purely empirical four constant formula which Bingham and Jackson (Bureau of Standards, No 298) give for fitting water from 0° to 100° shows an error of 1 4 per cent when extrapolated to − 9° C

is, in general, extraordinarily limited compared to, say, that available for surface tension there are, in general, no measurements above the boiling point at atmospheric pressure, and for low boiling liquids scarcely any at all below 0° C, which is in many cases, for example, pentane, the most important part of the range I am planning a series of investigations to be carried out in this laboratory, in the hope of adding to the reliable data for viscosity, more especially the temperature variation required to give b

Turning to the letters which have been sent to NATURE since my first letter was printed, the letter from my old friend Dr S E Sheppard, published on Mar 29, gives what is practically my formula and states one of my first results, namely, that for a large number of liquids the formula represents the observed data, within experimental error, over a wide range of temperature The complete independence of our work—our letters were written within a few days of one another, his in America, mine in England—may serve to emphasise the point that I wish to stress, namely, that this formula has a fundamental significance, and the constant b—Sheppard's k—has an intimate relation to the various properties connected with the internal energy of liquids The other points of interest which Sheppard raises are not the same as mine Sheppard has not made it quite clear how he obtains his a for associating liquids, for $\eta = Ae^{b/T}$ will not fit, for example, water Presumably, he has found the value of b by fitting one or two of the low temperature values I note that he has found that the formula has been already given by Senor J de Guzman in the *Anales de la Sociedad Española de Física y Química*, 1913 Prof Kendall has pointed out to me that he mentions it, in the form log $\eta^{1/8} = a/T + b$, in a footnote to a paper in the *Journal of the American Chemical Society*, 39, 1799, 1917 I have also, since deriving it, found that J S Dunn has given it in a short paper in the *Transactions of the Faraday Society*, 22, 401, 1926, as quoted in Mr E W Madge's letter Mr Dunn's paper had escaped my attention just as it has that of Dr Sheppard and his collaborators No particular attention ever seems to have been paid to the formula before, and it is not quoted in the standard books, for example, Hatschek's "Viscosity of Liquids" It is always distressing to find that one has been anticipated, in whatever degree, but it certainly does not seem to have been previously realised that the formula $\eta = Ae^{b/T}$ is fundamentally characteristic of normal liquids

As regards Mr E W Madge's formula, $\eta = \frac{A}{T-b}e^{\beta T}$, it does not seem to fit octane sensibly better than my formula with two constants, and it does not fit water so well as the formula $\eta = Ae^{b/T-\theta}$, with the same number of constants, which I quote earlier in this letter, variations as large as 1 5 per cent occurring in Mr Madge's table, as against 0 9 per cent over the same range with my simpler three constant formula If Mr Madge had computed the value for supercooled water at − 9 3° C, he would have found a discrepancy of nearly 5 per cent, as against 1 3 per cent given by $\eta = Ae^{b/T-\theta}$

Dr Frenkel's formula is scarcely, as he claims, "practically equivalent" to mine, for it is $ATe^{b/T}$, instead of $Ae^{b/T}$, and the multiplication by T renders it unable to fit the variation of viscosity with temperature, interesting as is its derivation

I am afraid I can attach but little importance to the fact, cited by Dr Black, that the formula does not fit commercial mineral oils, of no definite composition, in view of my success, confirmed by Dr Sheppard, in fitting a great variety of pure chemical substances I have investigated the type of variation from the formula shown by Dr Black's oils, and it is of a nature quite different from that shown by pure substances which do not fit, namely, such as associate strongly So far as I can learn, oils of this type often change their viscosity permanently on heating

Sir Ambrose Fleming's very interesting letter deals with the points which lie somewhat off the main current of my argument

I feel that some apology for the length of this letter is needed, but, even in this space, I have only been able to refer in the briefest possible manner to points connected with the subject which I have under immediate investigation

Catalytic Reactions at High Pressures

THE technical synthesis of ammonia by high pressure catalysis has given a great impetus to the development of high pressure reactions At the present time reaction pressures are confined to a few hundred atmospheres, at which pressures the technical problems in so far as material and construction are concerned may be fairly claimed to be solved Work in the high pressure laboratory at Amsterdam envisages operating pressures above ten thousand atmospheres and a few determinations of physical constants have already been made at pressures as high as 35,000 atmospheres At these pressures, again, especially at high temperatures, new problems of material, construction, and design will confront the engineer hoping to industrialise a process operating under these conditions Technical interest in catalysis at high pressures is at present focused on the numerous reactions involving the use of water gas as raw material and on hydrogenation of coal, including products derived from coal Many others involving processes of amination and oxidation are doubtless capable of development

Whilst the difficulties involved in the hydrogenation of coal are partly economic in character and lie partly in the variability of the raw material, these factors are not so important in many of the reactions involving water gas, and in that field it is clear that a whole series of careful physical chemical investigations are necessary before the state of affairs may be considered to be at all satisfactory

In developing the synthesis of ammonia, preliminary work involved the determination of the data necessary to establish the conditions of equilibrium of the system

$$N_2 + 3H_2 \rightleftarrows 2NH_3$$

over a wide range of pressure and of temperature This phase of the problem was in part simplified by the absence of other reactions in the combination of the two gases and by a knowledge, with fairly accurate data available, of the specific heats of hydrogen and nitrogen and approximate values for the heat of formation of ammonia, its specific heat and compressibility More accurate data have only recently been obtained, but the approximate data available before development of the industrial processes were sufficiently accurate

In the case of reactions involving water gas, the state of affairs is much more complex because there is a whole series of reactions which are possible with the gases carbon monoxide and hydrogen The initial

reactions which are important may be formulated as follows

$$(1)\ CO + H_2 \rightleftarrows HCHO$$
$$(2)\ CO + 2H_2 \rightleftarrows CH_3OH$$
$$(3)\ CO + 3H_2 \rightleftarrows CH_4 + H_2O$$

By aldol condensation together with stages of hydrogenation a whole sequence of higher aldehydes and alcohols may be obtained from (1), with the possible exception of ethyl alcohol

Accurate data on the heats of these reactions, on the specific heats and on the compressibilities of most of the products, are at present not available and in consequence the equilibrium under high pressures and over a range of temperatures for any one of these reactions cannot as yet be said to be determined with any degree of accuracy The work at the Imperial College on the experimental determination of the methanol equilibrium, reaction (2), appears to be the most complete at the present time Having obtained preliminary if not exact information on the conditions of equilibrium, the next stage involves the choice of a suitable catalyst, and here we note that apart from chemical reactivity the catalyst employed must possess the additional property of being highly selective in its action Whilst it is known from investigations that a copper catalyst favours reaction (1), a zinc oxide catalyst containing certain promoters, for example, chromium oxide, favours (2), and an active nickel catalyst is most suitable for the formation of methane, and that the rate of aldol condensation resulting in the formation of higher alcohols can readily be augmented by the addition of small qualities of alkali, the mechanism of the catalytic processes themselves which must contain the secret of the selectivity of these catalysts is unknown

Although the use of iron as a catalyst in the synthesis of ammonia has been known for nearly thirty years, it is only recently that any definite ideas as to what constitutes an active catalyst for this reaction have been developed These may be said to have originated in an examination of the activity of catalysts prepared by two different ways, as minute agglomerates and crystals formed as a result of condensation from the vapour phase, and by the breaking up of large crystals by processes of ' activation ' and prevention of the regrowth of the grain size by the addition of suitable materials

Developments along similar lines involving measurements both on the heats of adsorption as well as reaction rates in both forward and reverse directions may assist in the building up of a satisfactory interpretation of catalytic action From the discussion which was held at the Royal Society on Mar 20 on catalytic chemical reactions under high pressures, it was clearly evident that work both scientific and industrial in this important field is advancing rapidly in England, and in addition that the organic chemistry of the simpler aliphatic compounds was a field which requires immediate exploration by both physicists and physical chemists ERIC K RIDEAL

Historic Natural Events

April 14, 1912 S S *Titanic* sunk by Iceberg in Atlantic —During the months of April and May 1912, there was an abnormally large amount of ice off the Newfoundland Banks In April no fewer than 395 icebergs were counted south of lat 48° N, compared with an average number of 83, and in May 345 compared with an average of 130 The icebergs spread far to the south of their usual limits, and on April 14, the White Star liner *Titanic* struck one in lat 41° 46′ N, long 50° 14′ W, and sank with great loss of life As a result of this disaster, the first International Conference for Safety of Life at Sea was held in London in 1913, at which it was decided to establish and maintain a regular patrol of the iceberg area

April 15, 1077 End of ' Canossa ' Winter —The winter of 1076–77 was so rigorous in England, France, and central Europe that the oldest inhabitants did not remember a similar one The " Harleian Miscellany " records that " in the tenth year of his William the Conqueror's] reign, the cold of winter was exceeding memorable, both for sharpness and for continuance, for the earth remained hard from the beginning of November until the midst of April then ensuing " In Europe the snow lasted from Nov 1 to Mar 26, and the Rhine was crossed on the ice so late as April In central France hard frosts continued for four and a half months and the vines perished The passes across the Apennines were completely blocked by snow and ice It was from Jan 25 to 28, 1077, that the Emperor Henry IV of Germany stood shivering, bare headed and barefooted, and clad in a hair shirt, before Pope Gregory VII in the courtyard of the Castle of Canossa in northern Italy, before the Pope removed the ban of excommunication imposed for his harsh treatment of the Saxon princes

April 15, 1927 Mississippi Floods —The floods in the Mississippi valley in February–July 1927, because of their magnitude, protracted duration, and economic destructiveness, formed one of the greatest calamities of modern times Their beginnings may be traced back to the abnormal rains of September 1926 over the greater part of the Mississippi drainage area There were further heavy rains in October and November, and in December there were general floods in the southern streams tributary to the Ohio River The early months of 1927 also had a rainfall above the normal in most parts of the basin, but the most serious flooding did not begin until April 15, 1927, when a crevasse began to form in the levee guarding the river at Dorena, Mo, 30 miles below Cairo, Ill From that date the floods spread with terrible rapidity, and crevasses were formed in the levees The total area of lands overflowed was 28,573 square miles, and the damage was estimated as more than 284 million dollars The loss of life was 214, this (as well as the material loss) would have been far higher but for the warnings issued by the U S Weather Bureau

April 18, 1850 Tornado at Dublin —A violent thunderstorm developed at 3 30 P M, with hailstones as large as pigeon's eggs At 4 P M a tornado passed over, with hurricane winds from south east, which abruptly changed to north west A great deal of damage was done, in some districts practically every pane of glass was blown in, chimneys were overthrown, and roofs carried off, while many trees were uprooted. These fell to north west and south east in about equal proportions, adjacent trees sometimes lying in opposite directions The Cattle Show was in progress, and the cattle broke loose, leading to fearful confusion

April 18, 1906 Earthquake in California —The Californian earthquake on this day caused much damage in San Francisco, less by the shock than by the fires that followed it The most remarkable feature of this earthquake was the great length (not less than 270 miles) of an old fault known as the San Andreas rift along which the displacement occurred, reaching from Cape Mendocino on the north to near Monterey on the south Subsequent surveys of the district showed that the crust on both sides of the fault had moved, that on the south west side to the north west and on the other side to the south east

April 19, 1849 Snowstorm —There was heavy snow in south east England on April 16–20, and on April 19 the Westerham coach was buried and left all night in a snow drift on Titsey Hill

Academy of Sciences (*Comptes Rendus*, No 21, 1929) —**V Ambarzumian** Methods of determining the number of different atoms in the atmosphere of stars —**D I Eropkin** Determination of the absorption in the atmosphere of planets A new method is described which is based on the study of the influence of the atmosphere on the gradual decrease of the brightness of a satellite in the half shadow and in the shadow of the planet The method requires that the entire photometric curve of an eclipse should be interpreted, and it can be applied in practice only to the case of planets with bright satellites, for example, the earth and Jupiter —**V V Barovskii** A description of a new species of the genus *Malthodes* Kies (Coleoptera, Cantharididæ) of Central Asia *Malthodes grigorievi* sp n is described from Fergana, this is the first representative of the genus in the fauna of Central Asia —**N Olenev** Classification and geographical distribution of Ixodidæ (4) Descriptions of *Ixodes semenovi*, sp n from *Accentor collaris* (Scop) in Turkestan, and of *I redikorzevi lagurae* sbsp n, from *Lagurus lagurus* in the Lower Volga steppes, as well as a discussion of several other species —**N P Annenkova** A supplement to the polychæt fauna of the Black Sea (1) *Goniada bobrezkii* sp n This is the first representative of the family Goniadidæ known from the Black Sea

(*Comptes Rendus*, No 22, 1929) —**D I Mushketov** and **P M Nikiforov** A gravimetric and seismic expedition to Central Asia A preliminary account of the expedition is given The work with pendulums, gravity variometers, and seismographs was carried out at a number of points in the Fergana depression, and a lack of compensation was quite definitely established, the resulting tendency of the earth's crust to vertical upward displacements is the cause of earthquakes, which are not unusual in that locality As regards the origin of the Fergana depression, the conclusion was reached that it was formed as a result of squeezing of the earth's crust, the sial masses having been pressed into a denser layer underlying the crust —**P I Simanin** Contributions to the Culicid fauna of Fergana A list of twelve species of mosquitoes is given The number of setæ on the first joint of the valva is a doubtful specific character in the genus *Anopheles* —**D Beliankin** Titanium oxide in the dinas In a metallurgical oven, the titanium oxide of a dinas brick migrates towards the unaffected zone Analogous phenomena can be observed in the natural granites and porphyrites

Prague

Czech (Bohemian) Academy of Sciences and Arts (Second Class, Natural Science and Medicine), Dec 6 —Extraordinary meeting Prof J Matiegka gave a detailed account of his investigation concerning the identification of the remains of Jan Amos Komenský (Comenius) in the Church of Naarden, Holland —Ordinary meeting—**O Jirovec** The fauna of the digestive tract of the termite *Calotermes* species Greek —**O Jirovec** Nuclear division in *Trypanosoma evansi* —**C Čechura** Magnetic declination of Moravia and Silesia in the epoch 1925 5 —**V Špaček** and **B Zahálka**: Magnetism of the mountain Rip —**F Němejc** Palæobotanical researches on the quaternary flora of some localities in the vicinity of Růžomberk, Slovakia —**M Dillinger** A study of the maximum of current

occurring in the electrolysis of mercuric cyanide solutions with the dropping mercury kathode The electro-reduction of the non electrolyte mercuric cyanide in presence of electrolytes proceeds like that of oxygen, the maximal maximum occurring at a certain conductance, which is proportional to the concentration of mercuric cyanide The mercury cathode shows a considerable polarisation —**B Brauner** Comments to a former report on the analysis of water from the pond Babylon, Bohemian Forest

Rome

Royal National Academy of the Lincei, Nov 17 — **P Burgatti** The transformations of Lorentz A simple method is given for deducing Cayley's theorem, that the coefficients of a linear and orthogonal transformation in a Euclidean S_n are expressible rationally by means of $n(n-1)/2$ independent parameters —**U Cisotti** Types of rigid isolated profiles subjected to dynamic action by means of a local fluid current circulating round them —**N Parravano** and **E Onorata** 'Blanc' alumina Results are given which indicate the existence of what, in Wyckoff's terminology, must be regarded as a semi crystalline alumina, obtained by the thermal decomposition of hexa hydrated aluminium chloride, as well as of another alumina arising from the first at a higher temperature The former exhibits the double refraction characteristic of non monometric crystalline substances, whereas the second gives a distinct X ray interference spectrum pointing to hexagonal or rhombohedric symmetry The passage from the first to the second is accompanied by increase in density from 2 2 to about 3 5 and is, therefore, attended by approach of the atoms in the space intervening between the atoms of the unit cell Conversion of the second form into corundum also occurs with rise in the density (from 3 5 to 3 9) and with further approach of the atoms of the unit cell —**F Vercelli** The system of currents in the Straits of Bab el Mandeb in the summer —**E Bortolotti** Geodetic co ordinates along a line (1) —**R Calapso** A problem of the zero system osculatory to a congruence W —**Gr C Moisil** Movable datums in functional space —**O Onicescu** The asymptotic behaviour and the zeros of a class of entire functions —**G Supino** A criterion of choice between elastic solutions with equal resultants —**G Viola** The system of U Cephei The data collected on this system since 1913, particularly by Bemporad, are considered The mean light curve indicates asymmetry with respect to the minimum epoch, oscillations both during the phase of totality and at the beginning and end of the eclipse, and inconstancy of the maximum luminosity of the system —**E Fermi** The $4d$ complex of the helium molecule —**Giambattista Dal Piaz** New geological observations on the region lying between the Aurino torrent and the river Rienza (Upper Adige) (3) —**A Ferrari** and **F Giorgi** Crystalline structure of anhydrous iodides of divalent metals (1) Cobalt, ferrous, and manganese iodides These iodides exhibit structure of the cadmium iodide type The elementary cells have the following dimensions: cobalt iodide, $a=3\ 96$ A, $c=6\ 65$ A, $c\ a=1\ 68$, density, 5 75, ferrous iodide, $a=4\ 04$ A, $c=6\ 75$ A, $c\ a=1\ 67$, density, 5 39, manganese iodide, $a=4\ 16$ A, $c=6\ 82$ A, $c\ a=1\ 64$, density, 5 01 The dimensions of the unit cell of lead iodide, for which previous authors have given discordant values, are $a=4\ 53$ A, $c=6\ 92$ A, $c\ a=1\ 53$ —**L Maddalena** Utilisation of an interesting hydric level over the north east part of the plateau of Sette Comuni —**G Gabrieli** Two iconographic codices of plants in miniature, in the Royal Library at Windsor.

Diary of Societies

FRIDAY, April 11

Royal Astronomical Society, at 5 —R. O Redman The Galactic Rotation Effect in Late Type Stars
Physical Society (at Imperial College of Science), at 5 —Prof P Debye The Scattering of X Rays in Gases in Relation to Molecular Structure (Guthrie Lecture)
British Institute of Radiology (Medical Meeting), at 5 —Discussion on Radiology in Bone Tumours.
Royal Society of Medicine (Clinical Section) at 5 30
Malacological Society of London (at Linnean Society), at 6 —D F W Baden Powell Notes on Raised Beach Mollusca from the Isle of Portland —J R le B Tomlin Note on *Panopea cancellata* Sow —R Winckworth Description of a new *Chiton* from Karachi
Institution of Electrical Engineers (London Students Section) at 6.15 —Col Sir T F Purves Address
Institution of Chemical Engineers (at Municipal College of Technology, Manchester), at 7 —Dr W H. Hatfield The Fabrication of Acid resisting Steel Plant (Lecture).
Society of Dyers and Colourists (Manchester Section) (at Manchester), at 7 —C Hollins Patent Law and the Dyer
Oil and Colour Chemists Association (Manchester Section) (Annual Meeting) (at Old Rectory Club, Manchester), at 7
Junior Institution of Engineers, at 7 30 —W T Dunn Gas in Japan and the Far East.
Institute of Metals (Sheffield Local Section) (Annual General Meeting) (at Sheffield University), at 7 30.—F Russell Refractories and their Uses
Oil and Colour Chemists Association (at 30 Russell Square), at 7 30 —E Hatschek Some Properties of Jellies.
Society of Chemical Industry (Chemical Engineering Group) (at Chemical Society), at 8 —Discussion on Asphalt as a Chemical Engineering Material —A W Attwooll The Principles of Manufacture of Mastic Asphalt.—D McDonald Experience with Some Applications of Mastic Asphalt in a Chemical Works.
Royal Society of Medicine (Electro-Therapeutics Section), at 8 30 —Dr H A. Bulman, Dr L H Clark, Dr S. Russ, and Dr S. Wright The Physiological Effects of Penetrating X Rays upon the Cat and Rabbit.
Society of Dyers and Colourists (Manchester Section) (at Manchester). —Dr J L. Hankey Some Remarks on the Treatment of Aniline Black subsequent to Ageing
Paper Makers Association (Technical Section, London Division) (at Connaught Rooms, Great Queen Street) —J Strachan The Relationship Existing between the Tensile Strength and the Bursting Strength of Paper

SATURDAY April 12

Physiological Society (in Department of Physiology, University, Louvain), at 10 A M —G Debois : Glycogen Recovery after Mammalian Muscular Activity as an Insulin Function —C Heymans and J J Bouckaert Sinus Caroticus Reflexes upon Venous Pressure, Liver Volume, and Heart Volume.—P Rylandt Conduction in Mammalian Auricles.—J Morelle Calcium Shifting Experimental Rickets —J P Bouckaert, J L Petit, and J de Blende Variations in Muscular Viscosity —J P Host and H Ernould On the Nervous Control of Insulin Secretion.—P de Nayer Glycogen Deposition in Rabbit s Muscles —L. de Borggraef Ions and Excitability —E J Bigwood Chemical Properties of Gelatin Jellies. — Thomas The Nature of Blood Sugar —T Lewis Reaction of the Human Skin to Cold —Prof A. V Hill The Osmotic Pressure of Muscles —Dr W Cramer On Inhibition of the Adrenal Gland and Vitamin B Deficiency —Dr J F Fulton, Dr E G T Liddell, and D McI Rioch The Influence of Experimental Lesions of the Spinal Cord upon the Knee jerk and Crossed Extensor Reflexes —E W H Cruickshank An Adjustable Automatic Shaker for Gas Analysis —*Demonstrations* —F Malengreau Micromethod for Estimation of Bismuth in Biological Material —J Rutten Isoelectric Point of Bence Jones Protein —J Morelle Calcium Shifting Experimental Rickets —J P Bouckaert Determination of Muscular Viscosity — A. K M Noyons Differential Calorimeter

MONDAY, April 14

Royal Society of Medicine (United Services Section) (Annual General Meeting) at 4 30 —Surg Capt L M Morris Recruiting—A Review of Modern Requirements
Institution of Electrical Engineers (Informal Meeting) at 7 —A. B Eason and others Discussion on Telephone Exchange Practice in Germany and Scandinavia.
Institution of Electrical Engineers (Mersey and North Wales—Liverpool—Centre) (at Liverpool University) at 7 —Annual General Meeting
Institution of Electrical Engineers (North Eastern Centre) (at Armstrong College Newcastle upon Tyne) at 7 —Annual General Meeting
Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7
Institution of Electrical Engineers (Western Centre) (at Cheltenham) —Lt. Col S E Monkhouse and L C Grant The Heating of Buildings Electrically by means of Thermal Storage
Institute of Brewing (London Section) (at Charing Cross Hotel).—Discussion on The Brewing, Bottling and Pasteurisation of Beers
Royal Irish Academy (Dublin)

TUESDAY, April 15

Royal Society of Medicine at 5 30 —General Meeting
Zoological Society of London, at 5 30 —F J Lambert Animal Life in the Marsh Ditches of the Thames Estuary —Prof F Werner Indian Mantids or Praying Insects —W N F Woodland On the Genus *Polypocephalus* Braun, 1879 (Cestoda).—Major E E Austen On a New Dipterous Parasite (Family Calliphoridæ, Subfamily Calliphorinæ) of the Indian Elephant, with Notes on other Dipterous Parasites of Elephants
London Natural History Society (at Winchester House E C), at 6 30 —R. Palmer Some Aquatic Insects (Becot Memorial Meeting)
Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds) at 7 —Annual General Meeting

WEDNESDAY, April 16

Royal Meteorological Society, at 5 —Dr S K Banerji The Electric Field of Overhead Thunderclouds —Dr F J W Whipple The Great Siberian Meteor and the Waves Seismic and Aerial which it Produced
Royal Statistical Society (at Royal Society of Arts), at 5 15
Institution of Civil Engineers (Students Meeting), at 6 30 —P A. Scott Weymouth Bincleaves Firing Station, Repairing and Strengthening of Reinforced-Concrete Pier
Institution of Electrical Engineers (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7 30 —H S Carnegie The Selection of Electric Drive for Heavy Industrial Use
Folk Lore Society (at University College), at 8 —Dr R Flower The Ring of Sovereignty a Study in the Transmission of a Theme
Royal Microscopical Society at 8 —A Craig Bennett An Imbedding Apparatus for Research Workers —J Smiles The Measurement of Spherical Aberration in High Numerical Aperture Objectives by Interferometry

THURSDAY, April 17

Institution of Electrical Engineers (Hampshire Sub Centre) (at Municipal College, Portsmouth) at 7 30 —Dr C V Drysdale Alternating Current Potentiometers and their Applications.
Institution of Electrical Engineers (Irish Centre—Dublin) (at Trinity College, Dublin), at 7 45

ANNUAL MEETING

April 9, 10, and 11

Institution of Naval Architects (at Royal Society of Arts).

Friday, April 11 at 11 A M —R. Sulzer Causes and Prevention of Vibration in Motor Ships.
Dr J L. Taylor Vibration of Ships
Lieut.-Col F Dondona Sea Trials of Italian Flotilla Leaders
At 8 —G S Baker and Miss E M Keary Experiments on the Resistance and Form of Towed Barges
W C S Wigley Ship Wave Resistance—Some Further Comparisons of Mathematical Theory and Experiment Result

CONGRESS.

April 25 to 28.

Flemish Congress of Natural Sciences and Medicine (at Antwerp).

SATURDAY, APRIL 19, 1930

Pipe Lines and Progress

SLOWLY but surely the day of the individual, of the private firm, and of the small community is passing or has already passed The individual has parted with his liberties to the community, rationalisation is putting the private firm out of business, whilst the small town must participate in larger schemes if it is to supply such public utilities as water, gas, and electricity at satisfactory prices Thus we have a scheme for the national supply of electricity from super power stations already in being, and there is much talk of the long distance transmission of gas by trunk lines These would in the first place serve to interconnect all the existing gas producers in a given area of country, with the result that in time the main load would be supplied from the more economical plants, the others serving as a standby for conditions of peak load At the same time, the available productive capacity of the whole area would be greater than before, without any additional capital expenditure being required for new plant beyond that of the cost of the trunk lines All these considerations and advantages closely parallel those which it is hoped to attain in the electrical industry

It is surprising that a small country like Britain, in which distances are relatively so short, has not taken the lead in these matters it affords yet another proof, if such be required, of the inborn nature of British individuality The passage of our kin across the Atlantic, coupled more likely with the necessity for the co operative spirit in the development of the vast areas of a new and virgin country, has had the effect of making them super enthusiastic in developing large projects, and the very existence of distances has been seemingly accepted as a challenge to bridge and to make them as naught

The newest example of this spirit is exemplified in what is happening in regard to natural gas, which, though it can alas have no parallel in Great Britain, is well worth attention and study The great American oil industry to day has a capital of two thousand million pounds It has constructed in the United States some 100,000 miles of pipe line for the gathering and conveyance of the oil from the fields to the refineries and to the coast, the said lines contain at all times a quantity of oil estimated at 18 million barrels of 42 gallons each, they involve a very large annual expense for their maintenance and repair

At first the natural hydrocarbon gas produced

at the wells was largely wasted part of it was burnt near at hand as a source of heat part of it converted by processes which are none too efficient into carbon black which is an important ingredient of the rubber tyre

When the advantages of the gas as an industrial fuel became realised distance was regarded as no objection in running a pipe line to bring it to a potential large consumer Already some 60 000 miles of pipe line for natural gas are in existence and a very extensive programme of new construction is in hand The existing state of affairs is well shown in a large map of the natural gas pipe lines of the United States which is published by and can be obtained from the Department of Commerce

As showing the magnitude of the engineering problem involved and incidentally its beneficial effect on the steel industry it may be mentioned that in the line from Northern Louisiana to St Louis a total of 526 miles of 20 in and 22 in high pressure pipe were laid involving a weight of 115 000 tons of steel Much greater lengths than this are projected and natural gas is already beginning to reach the holders and distribution mains of the gas companies in the large cities of the Fast The natural gas has a calorific value of some 1000 B T U or roughly twice as high as that normally distributed by the gas industry problems therefore arise in regard to its dilution if it is to be burned efficiently in the existing domestic apparatus

It is claimed that already 75 per cent of the total gas burned in America is natural gas Questions naturally arise as to the permanence of any one source of supply as the wells become exhausted and the economic wisdom of the large capital sunk in the construction of the pipe it is the custom to write these off very rapidly The optimism of the American rises superior to any question of exhaustion—at the worst gas made from coal at super gas works astride the collieries can be pumped in the reverse direction through the mains is his answer

Indeed in the case of oil reversing the pipe line flow has already begun The original Pennsylvania field is largely exhausted so that the oil formerly sent from it by pipe line to be refined on the eastern seaboard has been replaced in the coast refinery by oil brought in from the Pacific Coast or Gulf of Mexico by ship such oil is being sent back along the pipe to be refined at Pittsburg and elsewhere Much more startling is the innovation to send finished petrol or gasoline as the Americans call it along a 371 mile pipe from the coast to Western Pennsylvania it is said that this will cost some 35 to 50 per cent less than the usual transport in tank waggons by rail

Naturally all sorts of problems have arisen in connexion with pipe lines the solution of which has been due to prompt and whole hearted co operation with scientific workers Soil corrosion is a most important matter even the aeroplane has been brought in to assist in making the first survey for the path of the line through rough country But for the production of better pipe and the development of welding methods which enable higher pressures to be used the transport of the natural gas such distances would not have been possible

The natural gas is obviously of very little value at the well so that its cost delivered into the holder of a city gas company even after full allowance has been made for the cost of pumping and the depreciation of the pipe is less than that at which gas of equivalent heating value can be manufactured from coal at the gas works This is of no disadvantage to the gas companies the co operation of which is essential to the success of any scheme for the introduction of natural gas seeing that one of the main items in the cost of gas to the actual consumer is that of the distribution from the point of manufacture

The lower the price at which gas can be supplied the more chance there is of its universal adoption as a source of heat its use whether by the house holder or in industry saves the worry connected with the purchase and storage of fuel to say nothing of the labour of stoking and the removal of clinker and ashes Most beneficial of all to the community will be the freedom from smoke in the cities

In Britain this last factor should appeal to us most of all but we have no natural gas and must therefore search in what other ways the price of the therm can be reduced There is every indication that the desirability of this is realised by the gas industry which apart from technical progress in the manufacture of gas in horizontal and vertical retorts is studying the use of gas from coke ovens from low temperature carbonisation and from oil refineries and cracking plants It would take us too far now to deal with the somewhat vexed question of the production of oil from coal in Britain—it has been achieved technically on the large scale though perhaps still a problem from the economic point of view Scotch shale cannel coal and the like will all eventually give their quota of oil and gas

On the continent of Europe the supply of gas

in bulk from coke oven plants in the Ruhr district over considerable distances has already made much headway, though it is understood that the original schemes to take gas as far as Berlin have been deferred Plans are also on foot to bring coke oven gas into Paris from a considerable distance

The problem in Britain is not altogether so simple as might appear The question of the cost of wayleaves for pipes and the assessment of these for rates by rural districts impose burdens which the consumer should not be asked to sustain if the nation has the production of cheap fuel and the lowering of costs in industry really at heart The proposal to locate super gas stations at the colliery also requires very careful examination, not every seam is suitable for gas making, whilst the ready marketing and cheap transport of the subsidiary products of the industry to the small consumer are factors of paramount importance

An Everflowing Stream

The Danube in Prehistory By Prof V Gordon Childe Pp xx + 479 + 57 plates (Oxford Clarendon Press, London Oxford University Press, 1929) 42s net

A BOOK of this kind has been long needed As Prof Childe notes in his preface, British archæologists, in addition to their own local antiquities, have found in the first cultures of the Mediterranean and the Near East happy hunting grounds and rich rewards There are historical reasons for that, and also for the comparative neglect of Central and even of Northen Europe Yet readers of Schliemann's works must have been impressed with the great mass of detailed work which had been done in these regions fifty years ago, however little they may have been convinced by his comparisons of this material with his own finds at Troy It must be admitted, however, that until recently the very abundance and perplexing variety of the data retarded the appearance of any such compendious handbook as Peet's "Stone and Bronze Ages in Italy" Even Hoernes' "Urgeschichte der bildenden Kunst in Europa", before its recent transformation by his pupil Menghin, was essentially a history of art (and particularly of iconic art), not of civilisation Latterly, the marked growth of popular interest in 'origins', as well as the necessity for some clue to such a labyrinth, even for specialists, has elicited summaries like Schuchhardt's "Alt-Europa", Tyler's "New Stone Age in Europe", and Prof Childe's own "Dawn of European Civilisation" But in so far as these attempted to cover the ground of Europe, and not stray far beyond it, they necessarily lacked scientific and historical, as well as literary unity What "The Danube in Prehistory" gives us is a series of intimate studies of a family, instead of a snapshot at a crowd The great valley now is no longer a corridor but a portrait gallery

Prof Childe is well equipped for his adventure His intimate acquaintance with museum collections and recent field work all over Europe, his command of the rather numerous languages in which the literature is scattered, and his previous surveys of the ground in his "Dawn" (already mentioned) and his "Aryans", give him advantages which he has here used to the full Above all, bulky as this book is, he has managed not to say too much, his characterisations of each phase of culture are graphic, and detach the really significant features from the bewildering details, and the comparisons, and inferences as to their meaning, which he has drawn, are so concisely stated, that it is only when one begins to know the book well that one discovers how much has been put into it

Very properly, an attempt to rationalise a microcosm of this sort, begins with a profession of faith, and there are few, if any, shorter and weightier statements of an antiquary's creed and code than the preface here Properly also, wild Nature frames the pageant of man's achievement the physique, and the principal external relations of the Danube basin with adjacent regions It would not have occupied more than a few additional pages, to indicate, still more concisely, what lies beyond the watersheds, even without anticipating by more than a phrase the peculiarities of the human contributions of each to Danubian cultures Without this, the significance of successive references to horse-bones, for example, will not be obvious to everyone

On the difficult problems of historical climate, and the sequence of plant regimes, what is said is cautious and trustworthy, but it would have been helpful to emphasise the contrasts between forest-regimes north and south of the valley, and still more between the vegetations that replace them respectively when drought sets in Beside the conspicuous contrast between superincumbent loess and older components of the structure, the petrological differences between different strata may seem slight, but there are phrases here and there which show that the author is aware of the marked peculiarities of 'karst' country, and the prevalence of this and other soluble rocks might have been

indicated, as well as the profound results of this, in the distribution of the types of plant covering already mentioned It is difficult, for example, to believe that the passes between Morava and Ægean were so long and so completely closed to mankind, as is represented here and hereafter, in view of the predominance of limestone country there, and this hypothesis is fundamental to the view taken in Chap iii of the course of the propagators of the culture known as 'Vinča I'

So little has been observed, hitherto, of the traces of palæolithic man in the Danube valley, that even the data collected in Chap ii (the extent of which will be a surprise to many) do not justify more than the most general inferences It is clear, however, that there was rather early admixture of brachycephalic types (p 14), so far back as Aurignacian deposits, and that consequently "the round heads of Ofnet do not necessarily betoken a fresh racial intrusion" (p 18) But in view of the general distribution of brachycephaly in Eurasia, Central European examples of it are surely intrusive, not aboriginal, whatever their date On the affinities of the long headed stock which seems to pre dominate on the loess land in early neolithic times, Prof Childe expresses no opinion, after recording several (p 45) His presentations of other folk's views are throughout commendably objective Only occasionally, even in descriptions, does a word of regret escape him, for example (p 58), on the French reluctance to take potsherds seriously, and (pp 166, 169) on delays in publication

The first neolithic culture, represented by the lower levels of the great *tell* at Vinča, has admittedly well marked resemblances with that of Anatolia Is it not, however, necessary to distinguish between neolithic Crete, for example, and the mainland sites, in view of Cretan and even Cycladic resemblances with early Sicily, Malta, and even Sardinia, and of the Egyptian glimpses of an indigenous neolithic culture in Libya Are 'East Mediterranean' and 'Anatolian' really convertible terms? Or is a good deal of the similarity among local cultures around the Ægean due to interpenetration of two distinct archetypes, one (in broad terms) indigenous to the north east, the other to the south-west, of a line from Alexandria to Rhodes? How that line is to be prolonged beyond the latter is gradually being revealed by recent work in Lesbos, in Macedonia, and south of the Corinthian Isthmus, and conclusions here may confirm or modify our interpretation of the course of events north of the Ægean

If Prof Childe is right in supposing that those who introduced 'Vinča I' culture into the Middle Danube came up the waterway, he may have to face the question whether such navigators came only from the Marmara shores, or from ports farther south To derive 'Vinča I' from fisher folk does less than justice to its emphatically agricultural character Whether the overland routes from the Marmara to the Middle Danube were really so impassable has been already doubted, and only further exploration in Thrace and Bulgaria can decide this point It must be admitted, however, that, on present evidence, early settlements seem to spread *up* the Morava, rather than downstream Jablanica—excavated too early to be quoted with confidence—seems to belong essentially to 'Vinča II', but it is noted (p 68) that Vinča itself may have remained conservative But on p 67 the possibility is after all admitted, that the beginnings of 'Danubian Ia' culture—more distant still to the north west—may be due to immigrants through Serbia, and the clay women nursing infants, in Danubian II, are "taken over from Thessaly and the Ægean" (p 70)

In the two 'Danubian' phases, outstanding controversies are as to the relations of 'Danubian I' with neighbouring cultures to the north west, in the Rhine valley and beyond, and of 'Danubian II' with the nascent civilisations of the Ægean, and especially of Thessaly The rich but inaccessible material from Butmir is put in a new perspective, as the work of an 'industrial centre', 'quite eccentric', and not 'originative', though it ran its own idiosyncrasies rather hard The recent Sumerian evidence for very early spirals in the south-east is naturally emphasised, yet it looks as if spirals, which originate in several ways, may also have originated in several places but Asia Minor is still almost unexplored, for early cultures

On the eastern margin of the 'Danubian' culture-areas lie the secluded 'painted-ware' settlements around Erösd with their perplexing resemblances to those of Ukraine, Bukowina, and Thessaly, and their 'poor cousins' injected into 'Danubian' surroundings so far off as the upper Tisza, on the frontier of Slovakia Here Prof Childe elaborates his earlier suggestion that these 'painted wares' are due to emissaries of the 'painted ware' culture of Sumeria But "frankly, many steps have to be interpolated", even if the queer "incineration necropolis" at Surghal in Babylonia be as closely like the *ploshchadki* sites of Kiev (which are neither cemeteries nor incinerated) as has been stated Once again, Asia Minor is unexplored, there have been surface-finds of early painted ware, but

Hissarlik eschewed painted ornament, and in Cyprus it is quite secondary On the other hand, the 'painted-ware' regime at its widest included Baluchistan and Mongolia, as Sir Aurel Stein and Dr Andersen have found, and the lower Volga is almost as unexplored as the Halys Meanwhile, is it certain that (p 110) 'Minyan ware' occurs at Cucuteni? One swallow does not make a summer, nor are all smooth iron-grey potsherds 'Minyan'

A whole group of intrusive cultures along the north side of the Danube basin owes its common characters to the interpenetration of two extraneous elements, the 'megalithic' culture of the Atlantic and Baltic frontage, and the pastoral regime of the 'battle axe folk' generally now derived from the Russian steppe As these cultures belong to the 'sub boreal' climatic phase, their spread was rapid, for the forests were now discontinuous, and grazing ground extensive Among the numerous controversies, Prof Childe picks his way discreetly, clarifying and supplementing he has coined one term, 'Danordic' (for cultures superimposed by Nordic intruders on Danubian aboriginals), which is likely to persist, and he offers one ingenious suggestion that the 'globular amphora' folk navigated the north German rivers, and in this way travelled far without losing characteristic 'megalithic' traits

These are only illustrations, all from the first half of this important book, of the kind of problem which the subject matter presents, and the lines on which a solution is attempted The author's candour and open mind are illustrated by his criticism of his own earlier views about the 'Pile dwellers' (p 171) Naturally many difficulties have to be confessed and left unsurmounted, until fresh evidence comes—a conspicuous example is in the chapter on the 'Corded ware' people—but those who have most to contribute will be the last to complain of that frankness, and the systematic arrangement, and clear distinction between facts and theories, secure to the book a permanent place, as a ground plan on which to lay out one's own superstructure, as time goes on We could have wished for even more illustrations, and especially for more of the quite excellent line drawings pot-fabrics are very hard to photograph, and impossible to represent fairly except by a series of examples And how comfortable it is to have all the line drawings from the same competent hand, whatever their ultimate source! The correlation diagram facing p. 418 looks like a cross word puzzle, but is easier to read when you know how The maps, though uniform in principle, and in the picturesque style of execution which finds favour now with the Clarendon Press, are not all equally eloquent, partly because some include too many kinds of data, partly because the symbols are not sufficiently contrasted But "The Danube in Prehistory" is a masterpiece in this kind of work J L M

A Chemical Dictionary

A Chemical Dictionary containing the Words generally used in Chemistry, and many of the Terms used in the related Sciences of Physics, Astrophysics, Mineralogy, Pharmacy, and Biology, with their Pronunciations, based on recent Chemical Literature By Prof Ingo W D Hackh Pp viii + 790 (London J and A Churchill, Philadelphia P Blakiston's Son and Co, Inc, 1930) 42*s*

THE present day intensely rapid development in all branches of natural science necessarily involves a growing terminology with which even the specialists find difficulties in keeping pace Particularly is this the case in chemistry, the encyclopædic nature of which scarcely needs remarking Apart from its laws and theories, chemistry has to deal with the elements, naturally occurring compounds, and with reactions, processes, and methods for obtaining the thousands of compounds continually being added to and produced as useful materials or as illustrative substances or as addenda of the science To treat of all of these is an enormous task by itself, if, in addition, a chemical dictionary attempts to make clear the interdependence of chemistry and the other branches of natural science—physics, biology, crystallography, and geology—and the arts of medicine and pharmacy, and also makes reference to those associated with the development of chemistry and the cognate sciences, it must attain a very considerable size and be frequently brought up to date if its usefulness is to be maintained

The production of a one volume chemical dictionary is, therefore, a great achievement, and Prof Hackh has rendered an important service to chemists and chemistry The volume is not too bulky to be handled conveniently and, for the most part, the information given is reasonably accurate and, in many cases, surprisingly detailed It is almost a super-dictionary, the author being rarely content to give a mere definition or description

It must be allowed that no dictionary will ever be found fully satisfactory in all details to all who may consult it The specialist in any one subject cannot expect to be satisfied with the necessarily

brief account given in a dictionary of those portions of the subject of which he can claim to be an authority It would not be surprising, for example, if even "The Oxford Dictionary" fails on occasion to satisfy the critical faculty of those cross word puzzle enthusiasts who are also readers of the *Times*

To illustrate the excellent features of Prof Hackh's dictionary would be impossible in a review of reasonable length, and reference can only be made to one or two Under 'hydrogen ion', there are, apart from the definition, a table of hydrogen-ion concentrations, references to and illustrations of hydrogen ion determinations by the electro metric and colorimetric methods together with a cross reference to 'indicator', where rather more than $2\frac{1}{2}$ pages are devoted to tables showing various indicators and the hydrogen ion concentration corresponding to the colour change in the cases of some 74 After the description of Paul Ehrlich as a German biochemist and the founder of modern chemotherapy, there is an outline covering $1\frac{1}{2}$ pages of Ehrlich's side chain theory and of other out standing features of his work It would be inter esting to discover how many organic chemists will familiarise themselves with the three pages of abbreviated structure formulæ of typical organic compounds, but this method of representation has saved many pages

Many 'articles' are illustrated by diagrams, for example, the triple point diagram for water is given under 'triple point', and the equilibrium diagram of the ternary system, lead bismuth tin, occurs under 'alloy' It would scarcely be reasonable to expect, but it would be useful to many readers to have, some explanation, however brief, of such diagrams, even if this could only be given by omitting illustrations of familiar apparatus such as an Erlenmeyer flask, a tripod, a burette stand, or even the photographs of chemists and physicists There is an adequate reference to 'parachor', even if the mathematical expression is inaccurate owing, possibly, to a printer's error The description of acetophenone in two places as 'benzoyl hydride' needs revision, and perhaps the author would have been well advised to omit at this stage the structural formula given to strychnine

The dictionary refers to the leading chemical societies, of which our own takes precedence on account of its date of foundation It also aims at being something in the nature of a chemical biography and, so far as living chemists are concerned, the present writer has gained the impression that the majority appear to be American Prof Armstrong is mentioned, but it may be regretted that his photograph does not appear on the opposite page to that of Arrhenius! We are tempted to wonder why there is no mention of H B Baker, W H Perkin, junr, R Robinson, J F Thorpe, R Willstatter, and H Wieland among chemists, and why J J Thomson and Eddington find no place in the gallery which includes Aston, Bohr, Einstein, Moseley, Rutherford, and C T R Wilson

There are, however, so many good points about the dictionary that one becomes perhaps unduly impressed by the relatively few defects, from whatever cause they have arisen, but which can easily be remedied in a future edition

The Oligochæta

The Oligochæta By Dr J Stephenson Pp xvi + 978 (Oxford Clarendon Press, London Oxford University Press, 1930) 60*s* net

THIRTY FIVE years ago the Clarendon Press published Beddard's well known "Monograph of the Order Oligochæta", but in the interval numerous investigations have been made on the structure, embryology, and physiology of these animals, and much more has been learnt of their ecology and distribution The time was ripe for a new monograph, and zoologists are grateful to Dr Stephenson for undertaking its preparation With the exception of Prof Michaelsen of Hamburg, it is doubtful if any other author could have successfully surveyed the whole order Dr Stephenson brought to the preparation of this work a thorough practical mastery of the structure and classification of the Oligochæta, an extensive knowledge of the literature and a flair for conciseness and clearness in presenting facts and conclusions, and he has produced a monograph of exceptional merit

The book consists of twenty chapters, a bibliography, a subject index, and a systematic index The first ten chapters give a systematic account of the external characters and of the structure, histology, and physiology of the various tissues and systems of organs—alimentary, vascular, excretory, nervous, and reproductive That on the alimentary canal includes consideration of the chromophil cells, the peptonephridia, and the calciferous glands which are produced by folding of the œsophageal epithelium, and are therefore not of mesodermal origin as some authors have suggested The chapter on the vascular system opens with an account of the arrangement of the blood vessels in *Lumbricus*, followed by a comparative consideration of each group of vessels in the Oligochæta and of their histology, concluding with a brief discussion of the

evolution of the vascular system in which the views of Lang (the trophocœl theory) and of Vejdovsky are set forth The following chapter on respiration gives a clear account of the mechanisms of respiratory interchange through the body wall—in which there may or may not be networks or loops of blood vessels—or by the agency of gills which are present in half a dozen genera, and of intestinal respiration which is met with in certain aquatic Oligochæta and to which the author devoted considerable attention some years ago

A description of the anatomy and histology of the Lumbricid nephridium prefaces the account of the half dozen main types of nephridia found in Oligochæta A systematic survey of the nephridia in the several families, a résume of the processes of excretion, and a brief note on the evolution of the nephridial system within the order complete a masterly exposition of a difficult subject

In the chapters on the nervous system the author has described the various neurones and their relations to one another and the remarkable giant nerve cells and fibres, has discussed the physiology of the nervous system in relation to the various types of locomotion, and has added a short note on the psychology of earthworms

The tenth chapter (115 pp), the longest in the anatomical part, is by far the best comparative account available of the gonads, their ducts and associated glands, the spermathecæ, the spermatophores, the modified genital setæ and the clitellum The three following chapters deal with spermatogenesis, oogenesis, fertilisation, copulation, oviposition, embryology, and asexual reproduction

In the fourteenth and fifteenth chapters are recorded the chief anomalies of structure and malformations, for example, bifurcation of one or both ends, and the principal results of investigations on regeneration and transplantation for which earthworms have been extensively employed

The following chapter on the ecology and manner of life of the Oligochæta contains a selection of the most interesting observations on these subjects from the literature of the last thirty five years, for example, reference is made to the very small oxygen requirements of certain aquatic forms—a species of *Limnodrilus* occurs in Peoria Lake (near Chicago) where the dissolved oxygen was found to be less than one part in a million—and to the number of earthworms in the soil, which appears to be considerably greater than was stated by Darwin The highest numbers recorded are for a meadow near Zurich, in which 700 Lumbricidæ and 8000 Enchytræids per square metre were found

The excellent chapter on geographical distribution deals clearly among other subjects with the views of Michaelsen and of Benham regarding the value of the evidence afforded by the distribution of Acanthodriline worms concerning the former existence of a more extensive antarctic continent The author adds his own careful conclusions on the bearing of the known facts of geographical distribution on the former existence of Indo Australian and other land bridges

The discussion of the phylogeny and affinities of the Oligochæta includes interesting observations on convergence and on polyphyly

In the concluding chapter, the author adopts a scheme of classification of the Oligochæta into fourteen families The Acanthobdellidæ are not included , they are regarded as leeches For each family a concise definition, a note of its distribution, and comments on the chief structural characters and on ecology are given The further systematic consideration is restricted to the genera—about 120—under each of which is a definition, reference to its distribution and a note of the number of species, with comments on special features The author states that the number of species of Oligochæta now known is about 2400, twice as many as were known in 1900, the revision of which would be a formidable task He makes a strong plea in the preface for the careful identification of specimens used in research and for the avoidance of such meaningless expressions as ' the earthworm ' or ' the common earthworm ', and points out that the phrase " the common earthworm, *Lumbricus terrestris* " is for many parts of the country fallacious, this worm being often less common than one or two species of *Allolobophora*

The bibliography of more than 1000 papers includes the most important works down to October 1928 and a few more recently issued Only about 80 bear date previous to 1895, the author rightly considering that the papers of an earlier date had been dealt with by Beddard or that the subjects of which they treat had been reinvestigated by newer methods

The illustrations have been carefully chosen, nearly all from recent memoirs A miscalculation of the number of earthworms per square metre from the figures per acre is the only mistake the reviewer has noticed, and the book appears to be entirely free from misprints The author is to be most heartily congratulated on his masterly monograph, which will undoubtedly be for many years the authoritative work of reference on the Oligochæta J H A

Our Bookshelf

Die Technologie der Fermente Herausgegeben von Prof Carl Oppenheimer Halbband 2 *Fermente in der Fettindustrie, Milchwirtschaft, Lederindustrie, Gelatine und Leimindustrie, Pharmaz Industrie, Malzextraktindustrie, Textilindustrie, Nahrungsmittelindustrie* Pp xi + 370 (Leipzig Georg Thieme, 1929) 42 gold marks

The work before us forms the completion of the fourth volume of Prof Oppenheimer's great treatise "Die Fermente und ihre Wirkungen" The fourth volume is entitled "Die Technologie der Fermente", the first half volume of which was compiled by Dr Albert Hesse of Munich The subject matter it dealt with may be gathered from its title, "Enzymatische Technologie der Gährungs industrien" The second half-volume, which is now under review, is concerned with the subjects given above under the sub title

The hydrolysis of fats on an industrial scale by the lipases is dealt with by Dr Emil Hoyer, whose article contains 17 illustrations Dr W Grummer's short article on enzymes in the milk industry is concerned with the technology of rennet A comprehensive monograph of 116 pages on the leather industry includes 21 illustrations and is contributed by Dr Otto Gerngross following which is a short article of four pages by the same author on gelatin and glue The article by Drs P Bergell and H Carls on enzymes in pharmacology covers 102 pages and contains five illustrations The concluding three articles are by Dr A Hesse, the subject matter being commercial malt extract, the significance of enzymes in the textile industries, and industries concerned with foods They occupy 13, 79, and 69 pages of text respectively

Throughout the work citations are made to scientific papers as well as to patent specifications

Prof Oppenheimer may be congratulated in having, with the help of his collaborators, produced an exceedingly valuable treatise on a department of science of ever increasing industrial importance

A R L

Vorkommen und Geochemie der mineralischen Rohstoffe Einführung in die Geochemie und Lagerstättenlehre, besonders für Chemiker und Studierende der allgemeinen Naturwissenschaften Von Prof Dr Georg Berg Pp x + 414 (Leipzig Akademische Verlagsgesellschaft m b H , 1929) 28 gold marks

In accordance with the modern tendency, Dr Berg regards the study of mineral deposits as 'applied geochemistry' His book, moreover, does not deal exclusively with ore deposits in the strict sense but includes deposits of all the useful minerals It is divided into two parts Part 1 consists of an introduction to geochemistry, and treats of the general factors underlying the distribution and migration of elements within the crust and interior of the earth, and the particular factors upon which their local enrichment to workable bodies depends In this part is given a good summary of all modern work on the subject

In Part 2 the elements are considered individually, although there is a primary grouping into certain classes, and in certain cases two closely related elements may be treated together The various mineral species are dealt with, and in every case the actual mode of occurrence is regarded as a function of all the geochemical characters of the element in question By this means the genetic relationships are made clear and the paragenesis of both elements and minerals takes on a new significance In a book of this nature it is quite impossible to describe every known deposit of each element nevertheless, the author has selected representative examples of the important types from world sources The text is illustrated throughout with numerous diagrams and sections

Travels in the Congo By André Gide Translated from the French by Dorothy Bussy Pp ix + 375 + 16 plates (New York and London Alfred A Knopf, 1930) 15*s* net

This volume, which is a translation of "Voyage au Congo" and "Le Retour du Tchad", published in 1927 and 1928, is the embodiment of an ambition realised after thirty six years It is appropriately dedicated to Joseph Conrad André Gide, the distinguished French man of letters, has here recorded the day to-day events and the impressions stored up in a journey by road and river, in boat and car, but mostly on foot, through the Belgian and French Congo to Lake Chad The reader should feel no disappointment at finding this no scientific record beyond an amateur interest in the more remarkable fauna of the tropics, and to some greater extent in the lepidoptera and flora, the author had not the equipment for systematic observation But nevertheless, as a vivid impressionistic picture of life and travel in tropical Africa, it has a value Native life and character stand out in the round against a background of the forest Though the author started, as he himself confesses, with little interest in the native and his relations with the white inhabitants and the administration, this soon became the main interest of the journey It is beyond question that his intervention brought to the notice of the administration many abuses in treatment of the natives by the commercial companies to whom concessions had been granted

Experimental Physical Chemistry By Prof F Daniels, Prof J Howard Mathews, and Prof J W Williams (International Chemical Series) Pp xvi + 475 (New York McGraw-Hill Book Co , Inc , London McGraw Hill Publishing Co , Ltd , 1929) 17*s* 6*d* net

Although there is no lack of good English text books on practical physical chemistry, the present volume forms a welcome addition to the literature of the subject It covers the range of experiments usually done by students in Great Britain, and gives in addition a number of alternative experiments of a more advanced character which will make the book useful to those beginning research There are useful references to literature The book should be available in every physico-chemical laboratory

Letters to the Editor.

The Parachor and Molecular Volume

DR SUGDEN has put physical chemistry very much in his debt by his introduction of the concept of the parachor Simply defined as this is in terms of Macleod's fundamental discovery that the surface tension of a liquid at any temperature is in a constant ratio to the fourth power of the difference of the orthobaric densities of liquid and vapour measured at the same temperature, the parachor has proved, as a weapon of attack on the problems of chemical constitution, much more powerful than the molecular volume

If we write Macleod's law in the form

$$\gamma^{1/4} = K(D - d),$$

the parachor P is simply the constant K multiplied by the molecular weight, putting, therefore,

$$P = M\gamma^{1/4}/(D - d),$$

it follows, as Dr Sugden rightly points out, that, if d is negligible in comparison with D, a comparison of the parachors of two substances is a comparison of two molecular volumes at temperatures such that the surface tensions are equal But the step from this argument to the assumption that a parachor (Sugden, *Jour Chem Soc*, 125, 1177, 1924, and T M Lowry, NATURE, Mar 8, p 364) " is in fact a molecular volume which is independent of the temperatures at which it is measured ", and which " therefore replaces, with greatly enhanced efficiency, the old molecular volumes " is quite unjustifiable

It is true that two speeds may be compared by comparing the lengths covered in equal times, but this does not provide the slightest justification for asserting that a length *is* a velocity Just as much, or as little, is a parachor a molecular volume, and one is not forwarding the use of this valuable concept by calling on it to play a rôle for which it is by no means fitted The parachor, as parachor, has assisted in the elucidation of a number of constitutional problems—there is nothing to be gained, and much to be lost, by rechristening it a molecular volume

The dangers attendant on this attitude are well illustrated by a study of a table drawn up by Dr Sugden He remarks (*Jour Chem Soc*, 125, 1177, 1924) that if the parachor " is a true measure of the molecular volume it should bear an approximately constant ratio to the critical volume ", and he gives a table, reproduced in extended form on p 31 of his interesting volume "The Parachor" which shows that the relation $P = 0\ 78\ V_c$ can be used to predict the molecular critical volume to within about 3 per cent Now, whatever we may think of the rational basis of Dr Sugden's hypothetical syllogism, we have good ground for assuming that the ratio P/V_c is *not* a constant Some little time ago, I showed (*Trans Far Soc*, 1923) that Macleod's constant C in the equation

$$\gamma = C(D - d)^4$$

may be expressed in terms of the molecular weight and critical constants of the liquid by

$$C = \Delta\theta_c/M^{2/3}\rho_c^{10/3}$$

where Δ is a 'universal' constant If we replace ρ_c by the critical molecular volume V_c and remember that the parachor P is equal to $MC^{1/4}$, we easily find that

$$P = \Delta_1\theta^{1/4}V_c^{5/6}$$

Hence it is not P/V_c which we should expect to be constant, but Δ_1, where

$$\Delta_1 = P/V_c^{5/6}\theta_c^{1/4} \text{ or } (P/V_c) \times (V_c^{1/6}/\theta_c^{1/4})$$

I reproduce here Dr Sugden's table with one or two additional columns, and if the columns headed P/V_c and Δ_1 respectively be compared, it will be seen that the constancy of the numbers in the column last mentioned is very considerably improved

Substance	P	V_c	θ_c	P/V_c	$\Delta_1 = P/V_c^{5/6}\theta_c^{1/4}$
Hydrogen	35 1	[46 9]	33 1	[0 75]	0 440
Methyl formate	138 6	172 0	487 1	0 81	0 406
Methyl acetate	177 0	227 8	506 8	0 78	0 405
Benzene	206 3	256 1	561 6	0 81	0 417
Carbon tetrachloride	219 9	276 1	556 3	0 80	0 418
Diethyl ether	211 7	281 9	466 9	0 75	0 414
Methyl propionate	215 0	282 0	530 5	0 76	0 407
Propyl formate	216 1	284 8	538 0	0 76	0 404
Ethyl acetate	217 1	286 3	523 2	0 76	0 407
Chlorobenzene	244 5	307 8	632 3	0 80	0 412
Methyl isobutyrate	253 3	338 9	540 7	0 75	0 409
Methyl butyrate	254 2	340 1	554 4	0 75	0 408
Ethyl propionate	254 8	344 3	546 0	0 74	0 405
Propyl acetate	256 1	345 3	549 3	0 74	0 406

The numbers for hydrogen are a little difficult to follow Dr Sugden gives the critical molecular volume of hydrogen as 46 9 Landolt Bornstein and the " International Critical Tables " agree in giving as the most probable value, Kamerlingh Onnes' figure of 0 03102 for the critical density This gives 64 5 as the critical molecular volume If now we take Dr Sugden's value of 46 9, the ratio P/V_c is about 0 75, but the value of Δ_1 is very far from the mean value 0 409 On the other hand, the accepted value of 64 5 makes the ratio of P/V_c equal to 0 53, but the constant of the last column is now 0 44, as close to the mean as one would expect with a substance such as hydrogen

There is very little doubt that it is preferable to treat the parachor as a parachor, and to discuss the problem of molecular volumes on an entirely independent basis As Prof Lowry remarks (in rather stronger terms than is justifiable) Kopp's attempt to regularise the values of molecular volumes by measuring them at the boiling points of the liquids concerned was not an unqualified success One has to remember however, that boiling points are only very approximately corresponding temperatures The ratio of boiling point to critical temperature varies, for example, in a perfectly regular manner for the homologous series of normal paraffins

It is possible—if indeed the attempt has not already been made—that a number of these irregularities would be removed if molecular volume determinations were carried out at exactly corresponding temperatures I have recently developed an equation showing the variation of the orthobaric density (ρ)

of an unassociated liquid with reduced temperature m, which takes the form

$$\rho = 2\rho_c[A(1-m)^{0.3} + (1-m/2)],$$

where A is a constant which to a first approximation may be taken as unity. With the exception of a few degrees in the neighbourhood of the critical temperature, this equation represents the behaviour of an unassociated liquid with an accuracy equal to that of experiment. The equation shows that, if comparisons be made at *strictly* corresponding temperatures, a comparison of molecular volumes reduces to a comparison of critical molecular volumes, and it is possible that regularities may emerge from a search made in this direction. However that may be, it is certain that a parachor is not a molecular volume. The parachor is a healthy infant, strong enough to fight its own battles in its own name, and its friends will be well advised to treat it as an independent concept.

Parasitism a Stimulus to Pupation. *Alysia manducator* in Relation to the Host *Lucilia sericata*.

CONSIDERABLE diversity of opinion has been expressed regarding the stage in which hibernation of the 'blow fly', *Lucilia sericata* Meigen, takes place. Records are given variously as:

(*a*) Mainly in the pupal, but also in the larval stage [1]
(*b*) Both in pupal and larval [2]
(*c*) In the larval stage [3]

In investigations in progress for the Australian Council for Scientific and Industrial Research, on the biological agencies which play a part in limiting the numbers of this fly, the question of hibernation has been brought into close apposition with that of parasitism by the Braconid, *Alysia manducator* Panzer.

Originally it appeared that hibernation of the host might take place in more than one stage, for both larvæ and puparia were recovered from the soil surrounding baits exposed in the autumn and examined towards the end of the season, five weeks later. The mean daily temperature from the time the larvæ had reached a stage of development normally leading to pupation, and for three weeks prior to examination, had been 8.5° C. As the daily range in temperature was small and the weather dull, the mean air temperature was no doubt a reasonable approximation to that of the soil to which most of the larvæ had migrated. Of the larvæ collected, some pupated a day or two after being brought to the laboratory, while others did not; the latter have undergone a tardy pupation on encountering higher temperatures, and the larval life of some of them at an average temperature of 15° C was prolonged to three months.

The mean temperatures obtaining in the field at the time the material from the bait was collected were such as are usually associated with hibernation. Thus it seemed highly improbable that the puparia taken from the field were those which would complete their development and produce flies before the winter. In other words, it appeared that hibernation might be possible in both larval and pupal stages. The parasitism records, however, have yielded some interesting results, which necessitate a different interpretation of the facts. From larvæ which had not pupated within eight days of being brought from the field the percentage parasitism has been negligible; practically all the parasitism records have been obtained from puparia or larvæ which pupated soon after collection, as will be seen from the following table:

TABLE I

Batch	Stage	Number	Parasitised	Parasitism
1	Larvæ	198	1	0.5%
	Puparia (plus larvæ pupated within 8 days of collection)	198	173	87.4%
2	Larvæ	70	6	8.6%
	Puparia (plus larvæ pupated within 8 days of collection)	128	119	92.2%

It appeared then, since practically all the parasitism was associated with those forms which had passed into the pupal stage, while those which remained as larvæ were unparasitised, that there might be some relation between host pupation and parasitism.

Of several thousand larvæ removed from the field a month earlier which had completed their development under cool conditions indoors, a proportion also had pupated, though the majority had remained in the larval stage. If, then, the relation which appeared to exist between parasitism and host pupation were a fact, it seemed reasonable to expect that confirmation might be obtained from those forms collected a month earlier, which, under cool conditions were apparently hibernating in part as larvæ and in part as puparia. One hundred of each stage were therefore dissected and the results were as follows. (One hundred larvæ left under the same conditions have continued to hibernate without pupation.)

TABLE II

Stage	Number	Parasitism
Larva	100	0 per cent
Puparium	100	88 per cent

As there was a possibility that the presence of parasites, more especially in the egg stage, may have escaped detection in the host larvæ, an additional hundred larvæ were put to pupate. (The parasite is present as a reasonably well developed larva after the host has pupated and its detection is therefore assured.) Of these, 87 pupated and 13 died. All were dissected. A further 100 puparia were also placed aside to emerge for confirmation of the species of parasite. The results from these extra larvæ and puparia confirm those already given.

TABLE III

Stage	Number	Parasitism
Larva	100	0 per cent
Puparium	100	89 per cent

It appears, then, that the retardation by low temperatures of the physiological events normally leading to pupation may be overcome by a stimulus contributed by parasitism.

Of the parasites obtained from the four groups of puparia given in the foregoing tables, *Alysia manducator* has predominated to the extent of 93.6, 99.1, 96.6, and 98.9 per cent respectively. The remaining parasitism was by *Aphæreta minuta* Nees, which appears to produce an effect similar to that caused by *Alysia*.

Altson [4] was of the opinion that 'successful para-

sitism ' by *Alysia manducator* caused the host larvæ to burrow, although he does not record any experiments on the point As most of his observational and experimental work was done on *Calliphora erythrocephala*, it was no doubt this species to which he referred One hesitates to accept the idea that ' successful parasitism ' by *Alysia manducator*, if this means the actual presence of an egg capable of development within the host, is the cause of stimulated pupation in *Lucilia sericata* It may be that the real cause is the secretion injected at the time of oviposition and which causes temporary paralysis of the host larva If this were the case it would probably account for some host pupation as a result of the injection without the deposition of the egg, and explain why in the foregoing tables all puparia did not yield parasites Interruptions in the oviposition act are common enough and due to a variety of causes Experimental work on this point is in progress

Penetration of Methylene Blue into Living Cells

IN NATURE of June 16, 1928 (vol 121, p 939), Irwin has commented adversely on certain quotations of my results on the penetration of methylene blue into living cells It seems important, therefore, to direct the attention of readers of NATURE to subsequent findings made by me

In these new experiments (M M Brooks, *Protoplasma*, 7, No 1, 46, 1929) it was found that differences between Irwin's methods and those used by me were responsible for differences in the results Irwin's experiments were done with a very much higher pH value of the external solution, a much more concentrated solution of dye in the external medium (from 3 to 25 times as concentrated), and a more impure dye, and in darkness rather than in diffuse daylight

Experiments done according to methods used by me again showed that methylene blue penetrates living cells as such and not as one of its lower homologs When Irwin's methods of experimentation were used, trimethylthionine was found in the sap, showing without doubt that her results were due either to high pH value which alters the dye, to the impurity or high concentration of dye which she used in the external solution, to the difference in illumination, or to some combination of these factors It is also important to consider what part is played by injury, plants placed under the adverse conditions of Irwin's experiments are undoubtedly more abnormal than those subjected to such mild treatment as that used by me

There is no reason to doubt the validity of the spectrophotometric analyses made for Irwin by W C Holmes and K S Gibson of the Bureau of Standards, Washington, D C The error lies in the solution which was submitted to them for measurement

It is apparent that the purer the methylene blue, and the less abnormal the experimental conditions, the more nearly will methylene blue be found uncontaminated in living cells

Discussion of contradictory results obtained by different workers will scarcely advance our knowledge of cellular biology unless due consideration is given to possible differences in experimental methods It is a simple matter to confirm the observation that methylene blue as such penetrates normal living cells, provided proper methods are used

Photo-Decomposition of Molecules having Diffuse Band Spectra

THE products of photo decomposition of molecules showing diffuse discontinuous band absorption spectra (predissociation spectra) where, according to Bonhoeffer and Farkas (*Z physik Chem*, 134, 337, 1928), the light produces dissociation by internal energy exchange, without collision, can be studied readily in the case of ammonia

If ammonia at a few millimetres pressure be introduced into a quartz tube containing the yellow tungstic oxide and the gas be illuminated with a hot mercury vapour arc, reduction to the blue oxide of tungsten occurs with a few minutes exposure This ready reduction points to the presence of atomic hydrogen in the decomposition products The result is not unequivocal, since there might be (Bates and Taylor, *J Am Chem Soc*, 49, 2438, 1927) hydrazine formed in a stepwise decomposition of the ammonia, and it is known that hydrazine reduces tungstic oxide at room temperature

The formation of atomic hydrogen is, however, indicated by the following experiment Mixtures of ammonia gas, hydrogen, and carbon monoxide when streamed through a quartz tube illuminated by the mercury arc produce marked quantities of formaldehyde and also a considerable deposit upon the sides of the tube of a white solid, soluble in water, which appears to be hexamethylene tetramine This reaction definitely points to a dissociation of ammonia yielding atomic hydrogen, since the activity of this latter in producing formaldehyde from hydrogen and carbon monoxide is well known (Taylor and Marshall, *J Phys Chem*, 29, 1140, 1925) This method of producing atomic hydrogen in controlled amounts by regulating the intensity of illumination of ammonia and other molecules showing diffuse spectra is well adapted to the study of reactions induced by introducing atomic hydrogen in various gas mixtures Such studies are in progress here

Intensities in the Atmospheric Oxygen (Intercombination) Bands

WE have made exact intensity measurements of the *A* group of the absorption bands of oxygen at λ7600 A with the aid of the ' raster ' method of Frerichs,[1] using a 6 4 metre concave grating, infra red sensitive plates, and three different lengths of light path, respectively 14, 33, and 60 metres It was found that the exponential absorption law $J = J_0 e^{-kd}$ holds for these absorption lines, for the 33 metre light path, assuming that the peaks of our photograms can be identified with the true absorption co efficient, we find for the strongest line an absorption $\frac{J_0 - J}{J_0}$ of 27 per cent

Knowing the temperature of the absorbing gas (air, room temperature) and the true energies of the

rotational levels[2] it is possible to compute the transition probabilities of the rotational levels, since the Boltzmann factor is exactly known According to Mulliken, these bands are a $^1\Sigma - {}^3\Sigma$ combination, the ground level of the molecule being the $^3\Sigma$ state The lines obey the following relations

$$P_3(j) = F'(j) - F_3''(j+1), \quad R_2(j) = F'(j) - F_2''(j-1)$$
$$P_2(j) = F'(j) - F_2''(j), \quad R_1(j) = F'(j) - F_1''(j)$$

The intensity relations (not hitherto known for intercombination bands of this type) which are found to hold are as follows (omitting the Boltzmann factor $e^{-E/kT}$)

$$\text{Intensity of } P_3(j) = \tfrac{1}{2}(j+2) \qquad R_2(j) = \tfrac{1}{2}(j-1)$$
$$P_2(j) = \tfrac{1}{2}(j+1) \qquad R_1(j) = \tfrac{1}{2}(j)$$

For small values of j, there are small deviations which we believe to be real and which are proportional to reciprocal values of j The summation rule $P_3(j) + P_2(j) + R_2(j) + R_1(j) = 2j + 1$ is therefore obeyed only for the higher values of j The mean error of the measurements, of which a full account will be given later in the *Zeits f Phys*, is about 3 4 per cent

The Hybridity of *Drosophila melanogaster*

I AM very much attracted by Prof Jeffrey's remarks in NATURE of Mar 15 on the hybridity of *Drosophila melanogaster*, partly because I also think hybridisation (internal or external) of great evolutionary importance But the tangle of genetical and cytological literature has obscured so many of the issues involved that I feel Prof Jeffrey would do us a great service in elaborating some of his ideas and defining others

What, for example, is a hybrid? How are we to define it and how are we to recognise it? These are questions that Prof Jeffrey with his clear cut ideas will be able to answer directly The working geneticist and cytologist cannot deal with them so easily He cannot see the wood for the trees

One would like to know also in simple terms how variation is connected with hybridity in, say, *Drosophila melanogaster* and *Œnothera Lamarckiana*? Is it what Mendelians call 'segregation'? Or is it due to crossing over? Or can we perhaps ascribe it to an irritability of the germ plasm induced by the hybrid condition? If we knew these things we might be able to make some notable generalisations

Again, with regard to the pairing of chromosomes, I agree with Prof Jeffrey in attaching great importance to failure of pairing, but I hesitate to give it a general cause Does it happen for the same reason in *Drosophila*, *Œnothera*, *Drosera*, and *Tradescantia*? Perhaps Prof Jeffrey can show that it is always due to hybridity, and that will be a great help in understanding meiosis Perhaps he can show, also, that lagging chromosomes are always due to the same condition

Finally the student would like to know what Prof Jeffrey thinks of the criticisms of *Drosophila* workers, such as Metz, Bělař, Huettner, Guyénot and Naville, and Zuitin Are their suggestions, that Prof Jeffrey's lagging chromosomes in *Drosophila* are really cytoplasmic bodies, to be taken seriously, or are they merely irrelevant?

Raman Effect in Water

IN a previous communication (NATURE, Nov 16, 1929) the peculiar changes in the Raman bands for water in solutions of nitric acid were mentioned Work with many other strong electrolytes, acids, bases, and salts, has confirmed this behaviour Study of the bands with ice and with water at higher temperatures has revealed interesting features connected with this Pure water gives three bands corresponding to infra red wave lengths of about 3 12, 2 93, and 2 79 μ, which are diffuse and merge into one another In electrolytic solutions, however, these three bands become sharper with increasing concentration of the electrolyte The band corresponding to 3 12 μ gradually diminishes in intensity until, in very concentrated solutions, it entirely disappears On the other hand, the band corresponding to 2 79 μ, which is the weakest of the three in pure water, becomes stronger in intensity with increasing proportion of the electrolyte, until, in very strong solutions, it becomes equal in intensity to the central band, which is the most intense of the three in pure water

A study of the variation with temperature of the distribution of the intensities of these three bands has shown a similar behaviour, the band corresponding to 3 12 μ diminishing in intensity with increasing temperature, while that for 2 79 μ increases Crystalline ice has shown an entirely different behaviour The intensity of the central band is the same as in water But the band corresponding to 3 12 μ is stronger in intensity than in water, the band for 2 79 μ being weaker still in ice Thus the behaviour of water in electrolytic solutions, instead of being similar to that in crystalline ice, is exactly opposite to it It behaves more like water at higher temperatures This is a surprising result, being contrary to existing ideas regarding the nature of water in solutions

Dipole Moment of some Organic Halides

IN a note published in NATURE (Mar 16, 1929), Prof P N Ghosh pointed out from the results of Mahanti and Das Gupta (*Ind Jour Phys*, 3, 467, 1929) that the OH radical is mainly responsible for producing the dipole moment in the case of the saturated normal alcohols, whether the carbon chain is open or closed, long or short Recently (in a paper communicated to *Phys Zeit*) Mahanti has shown that the dipole moment is sensibly constant for a homologous series and its magnitude depends on the nature of the polar group, radical, or atom in the corresponding homologues According to his view, all the alkyl chlorides should have a dipole moment of the order of 2×10^{-18} e s u and the bromides of the order of $1\ 79 \times 10^{-18}$ e s u I have determined the dipole moments of a few organic halides by a heterodyne method and they agree well with the views and results of Mahanti They are

Earth Movements in the Delta of the Rhone

By R D OLDHAM, F R S

DELTAS are essentially areas of instability The very existence of a large delta is dependent on changes of level of the land, and not merely a general subsidence, but a special local sinking of the deltaic region in comparison with the surrounding land Nor is this all, for there can be few deltas, if any, in which the general movement in a downward direction has not been interrupted at intervals by one in the opposite direction, and in which more or less extensive areas of upraised alluvium cannot be found To this rule the delta of the Rhone is no exception, but there is no other instance in which the amount of this change can be measured, or the date fixed at which it took place, with so close a degree of accuracy as can be done for some of the changes which have taken place at the mouth of the Rhone

Readers of NATURE may remember that this subject was referred to in articles on "Problems of the Rhone Delta", which appeared in the issues of July 4, 11, and 18, 1925 It was there pointed out that the geological work of M G Denizot had demonstrated an uplift of the land in the pre historic past, by which the original alluvial deposit of the delta was raised to a level at which further accretion was brought to an end and an undulating land surface developed by denudation, a surface on which the Romans built their homes and monuments, and of which large areas are still in evidence, though a larger part has been buried under fresh deposits of alluvium formed at a later date It was also pointed out that there was evidence of a subsidence of the land, amounting to about 5 metres, having taken place between the beginning of the eighth and the end of the ninth centuries Since those articles were written, I have been able to collect a much larger volume of evidence bearing on the problems indicated in the earlier articles, and an epitome of the results, as they affect this question, of past changes of level, will probably be of interest

The position of the mouth of the Rhone in Roman times can be fixed with certainty and a fairly close approach to precision from the maritime itinerary, first compiled in the first or second century of our era It lay sixteen Roman miles from the port of Fossae Marianae, now represented by the seaside resort of Fos-sur Mer, and this would bring it to the locality where is now the Grau de la Dent at the mouth of the Vieux Rhône, or channel occupied by the river during the seventeenth century, the existing sea coast being at this point almost coincident with the ancient shore line of pre Roman and early Roman times At Arles the channel of the Roman Rhone seems to have followed very closely the course of that in which it now flows, and local conditions preclude any wide departure from it At about ten kilometres below Arles the channel can again be fixed within narrow limits, a spur of the gravels of the Crau puts an absolute bar on any course lying east of the present one, and within less than 3 kilometres to the west comes a spread of the old pre Roman land surface carved out of the upraised alluvium Within these narrow limits the Roman Rhone must have flowed, but below this there is no certainty, except that it never flowed past Passon or by any of the channels below that point, which have been followed at various times from the twelfth century to the present day The most likely interpretation is that it followed the general course of the present Aube de Bouic to near the shore of the Étang de Vaccarès, thence southwards to the east of Fiélouse and the ruins of the Abbey of St Ulmet, and then to the same general course as was followed by the last 8 or 10 kilometres of the seventeenth century channel, which is still known as the Vieux Rhône Measured along this course, the thirty Roman miles given in the itinerary as the distance by river from the mouth to Arles, would correspond very closely with the actual length of channel

With the end of the Roman dominion the records become scanty and fragmentary, until the close of the twelfth century, when we find an entirely different state of things The seaport of Fossae had disappeared, the entrance to the main channel of navigation was at the mouth of what is now the Étang de Galéjon, on the western shore of which there is a group of low hills, then known as Odor, and later as La Roque Passing this a broad stretch of inland lagoons was traversed to the neighbourhood of Passon, where further progress was only possible along a single channel, narrow and barely deep enough to admit even those vessels of small tonnage by which the bulk of the sea traffic of those days was carried This channel, known as the Grau de Passon, led into a wider and more open one coming down from Arles, and was the cause of constant anxiety to the council of that city, for fear that it might become blocked by obstacles to navigation Though called a 'grau', which at the present day would suggest the mouth of a river, the condition in the twelfth century was different, it is clear from later history that the real river did not flow this way, and did not reach the so called grau until after the thirteenth century had run its course The channel was a passage between two lagoons, through which little or no current flowed, and the question arises of how it could have originated It is certain that nothing of the sort existed in Roman times and that the track of vessels bound for Arles did not then run up the Étang de Galéjon, and through that channel which is crossed by the railway from Arles to Port St Louis, immediately south of the station of La Porcelette Here a small irrigation canal, deriving from the river, is all that remains to mark what was once the main channel of navigation from Arles to the sea, then for a while of the river itself, continuing ultimately as a distributory until it was artificially closed, somewhere about 1640, and ultimately converted into an irrigation canal There is but one way in which a narrow channel lying, as this did, between broader

spreads of water could have originated, and that is a general subsidence of the country and submergence of the lower levels, the narrow passage was across the strip of higher ground, known as the Plan du Bourg, which may be described as the backbone of the country east of the Rhone Besides the Grau de Passon, at least one other channel was opened across this barrier, but neither it nor any other, if such there were, was as deep or convenient for navigation

Here, then, we have a definite means of measuring the amount of subsidence which took place In Roman times the ground level of the bed of this channel must have stood above the flood level of the Rhone, and at the present day the flood waters of the Rhone near Passon reach a height of about 2 75 metres, from which we may conclude that the bottom of the channel must originally have been about 3 metres above the mean sea-level of Roman times

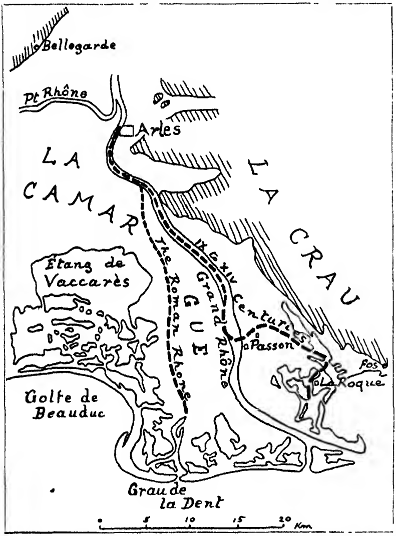

FIG 1 —Map of the eastern delta showing the main channel of navigation between Arles and the sea in Roman and in early medieval times The change from one to the other took place in the eighth century A D the eastern channel became blocked by the advance of the river about the end of the fourteenth century The course of the Roman Rhone across the Camargue has not yet been worked out in detail, that shown on the map is merely approximate

The depth of the channel at some time not later than the end of the fourteenth century was such that the bottom stood at about 2 75 metres below mean sea-level, and in the twelfth century would probably have been somewhat, though not materially, below this Adding these two together, we have proof of a change of level amounting to nearly 6 metres in all, for, taking the shallowest part of the channel, where the solid land rose to its highest level along the depression, we find that a spot which up to the fifth century had stood about 3 metres above sea level, in the twelfth lay about the same height below it, and this could only come about through a change in the relative height of land and sea, which may be described as a sinking of the land, or a rise of the sea, level, according to the point of view Four years ago this figure seemed excessive for the town of Arles, where remains of Roman structures on the banks of the Rhone show that here also there has been a change of level, which appeared to have amounted to about 5 metres, but not more than that In October last, however, when visiting Arles, I found the river standing at an unusually low level, and was able to examine the remains on the western bank more thoroughly than had previously been possible, with the result that the amount of change since Roman days must be raised to a figure of quite 6 metres, or possibly more From this must be deducted an allowance for subsidence which took place in the eighteenth century of from a half to a whole metre, so that the evidence at Arles and at Passon confirm each other in showing that the eastern delta along the present course of the Rhone stood somewhere about 6 metres lower in the twelfth than it did in the earlier centuries of our era Subsidence of this amount, in a region of such low-lying land and such low relief, must have had one result, that large areas of the lower levels would permanently sink below the level of the sea, and, as a further consequence, there would come into being a large area of shallow waters through which the river could extend its new delta with great rapidity These new lands so formed gave rise to a number of disputes over their ownership, and from the evidence recorded and the maps which were made to illustrate the claims of one party or another, it has been possible to reconstruct the main outlines, and in some cases even the details, of the geography

of the country as it stood after the subsidence was complete, but before the river had re established itself in its former territory The result, however, has only been attained after a considerable search among the ancient records, made possible by the care which is taken in France of their archives and the unfailing courtesy of the archivists in charge

The date at which this subsidence took place is as important and interesting as the amount, and so far as the eastern delta no new evidence has appeared beyond that referred to in the earlier article At the beginning of the eighth century the port of Fossae Marianae—which by this time had dropped the second word of its title—was still a mart of importance, a port of destination for sea borne commerce and, presumably, of transhipment into river going craft Its character was still the same as in Roman times, and we may conclude that the subsidence had either not yet commenced or, at any rate, had not gone far enough to affect the status of Fossae From the middle of the ninth century we find the Passon channel in full use, and nothing more is heard of Fossae as a seaport, for it had been superseded by Arles, which had become a port of destination for the overseas commerce of those times The bulk, if not the whole, of the change of level must have taken place between the commencement of the eighth and the latter half of the ninth century, and in the eastern delta the limit cannot be more closely drawn, but if we turn to the western delta we find that it also underwent a change of level comparable in amount with that which affected the eastern, and a charter of the year 788, conveying a grant of land to the Abbey of Psalmodi, shows that the subsidence, if not complete, was at any rate far advanced at that date As the grant out of the customs of Fossae, made to the Abbey of Corbie in 716, shows that the subsidence had not yet made much progress, the two together put the bulk of the movement as having taken place within the limits of the eighth century, though doubtless overlapping it at either end, and this brief period of rapid change of level came between two much longer periods of little or no change

Interesting as this would be in itself, it is by no means the whole story, for the maps of the eighteenth century make it clear that the latter part of that period saw a renewal of downward displacement of the level of the land, of shorter duration in time than that of the eighth century, and smaller in amount, the total change of level having been no more than a metre in all, and possibly less More interesting, however, than this, is the distinct suggestion of a change of level, not very different in amount from that of the eighth century, having taken place somewhere about a thousand years before our era The "Ora maritima" of Avienus, after describing the course of the Rhone from its source in the mountains, says that it enters a great marsh and mere, known in ancient times as Accion, and then, resuming its character as a river, gives off a branch towards the west On this follows immediately the mention of the bifurcation of the river and of Arles, from which it is easy to fix the position of the lake Accion Hereabouts it is known that there was a great spread of water in the Middle Ages which has largely been silted up, disappearing finally when the canal from Aiguesmortes to Beaucaire was constructed This drained away the permanent standing water, and all that is left to preserve the memory of a lake which had been important enough to be shown on a portolan map of Petrus Vesconte, is a tract of marshy ground, lying east of Bellegarde Though occupying the same position, this medieval lake cannot be accepted as a continuation, but must rather be regarded as a successor of that mentioned by Avienus, though not by the Roman geographers of the first century or by later writers, even those contemporaneous with Avienus himself In this there is nothing either of contradiction or inconsistency, for the "Ora maritima", though composed in the fifth century, was avowedly based on an ancient record, which modern scholarship has recognised as a Greek 'periplus' of about 600 B C, revised in part and at intervals of later date It is to this period that the lake Accion must be referred, which

FIG 2—Map of the seaward portion of the eastern delta, as it was from the ninth to the thirteenth century The representation is necessarily approximate and somewhat diagrammatic, the actual outline must have been more intricate, and many small islands, not shown, must have existed but nothing is represented for which there is not some authority and nothing of material importance is likely to be missing *B*, *T*, *G*, *L*, sites of the Tours de Bolovard (1469) Timpan (1606) St Genest (1656), and St Louis (1736) built by the town of Arles to guard the channels successively adopted by the Rhone

had dwindled, in later Roman times, to a condition not unlike that of the marshes of Bellegarde before they were drained in the eighteenth century History, in fact, seems to have repeated itself twice in this period, and the great spread of water which may be inferred as having been originated by the eighth-century subsidence, was preceded by a similar one, resulting from a subsidence, not greatly

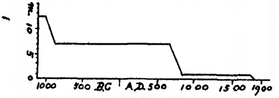

Fig 3—Variations, during the last 3000 years, in the height of the Rhone delta above sea level

differing in magnitude, at somewhere about 1000 B C In both cases succeeding centuries saw the lake gradually diminishing as it became filled up and narrowed by the alluvial deposits of the Rhone

Accepting this interpretation we may draw a graph of the level at which the delta stood, relative to the present level of the sea, for the period during which there is any historical record The result is an instructive and interesting one, for we see that, while the change has been always downward, uninterrupted by any appreciable upward movement during the last three thousand years, it has not been slow and continuous, but limited to three periods during which the change was more or less rapid, separated by much more prolonged periods during which no change took place, or only to an inappreciable extent

It is natural to inquire whether these changes were localised in the delta of the Rhone, or formed part of a widespread change in the level of the Mediterranean It is scarcely possible that a change of 20 feet at Passon would not have extended so far as Fos, only ten miles away, and this may well be the explanation of the fact that an important and prosperous town, such as was Fossae Marianae in its prime, has left no remains of buildings adequate to its former importance, the site of the docks, warehouses, and public buildings having sunk beneath the sea Farther afield, however, the evidence becomes contradictory and unconvincing, on one hand there is the existence, at several places along the coast, of Roman constructions, which archæologists have described as the remains of piers, harbours, and fish-stews, but the interpretation is a matter of opinion and open to argument, on the other hand, there are structures which must originally have been built above sea level, and are now partially submerged, but none of these gives positive proof of more than a very few feet of change, though they are not inconsistent with movement of larger amount The question calls for fuller investigation, and until this has been carried out it is impossible to assert that the changes of level which can be recognised in the deltas were not localised to that region, for the present they cannot with safety be regarded as having any bearing on the question of whether there has been a widespread change in the relative level of land and sea, affecting simultaneously and as the result of a common cause any large fraction of the Mediterranean, to say nothing of the Atlantic Ocean as well

Diet and the Teeth [1]

In the course of Prof E Mellanby's researches on rickets in dogs, which led to the discovery of the antirachitic vitamin, now known as vitamin D, it was noticed that defects in calcification were not confined to the long bones, but occurred also in the jaws and teeth of animals maintained on defective diets Mrs Mellanby followed up this point, and during the last decade has published numerous papers upon the influence of the diet upon the teeth, and also upon the relationship between dental structure and disease A detailed account of this work is in preparation, and is being published in three parts the present volume is the first of the series and is being followed by Part II, upon dental structure in other animals than the dog, and upon the production of dental disease, and by Part III, upon the structure of human teeth and the relationship between structure and caries

The dog was selected as the experimental animal of choice, since wide variations of dental structure can be readily produced it is, moreover, omnivorous, like man, and can be readily kept in health under strict laboratory conditions, it is easy to handle, and its teeth can be readily examined at any time Like man also it shows a deciduous and permanent dentition

The report describes in detail the various points to which attention was paid in each of the experimental animals, notes were made of the general health as well as of the condition of the mouth, macroscopic examination of the teeth and radiographs of the jaws and teeth during life were followed by microscopic examination of the teeth and related structures post-mortem, special attention being directed to the large carnassials in the upper and lower jaws The various grades of calcification are best studied in photomicrographs of ground sections of the teeth, of which numerous excellent reproductions are included in the report, at the same time enlarged photographs of the crowns readily show up deficiencies in calcification of the enamel

The standard basal diet used throughout had the following composition cooked cereal 100-200 gm., separated milk powder 10 30 gm, raw 'lean' meat 10-20 gm, oil or fat 10 c c, orange juice 3 5 c c, brewer's yeast 5-10 gm, and sodium chloride 1-4 gm If 3 c c of the oil consists of cod-liver oil, perfect health and perfect dental structure are observed, indicating that the diet is now adequate Small quantities of fat-soluble vitamin occur in the milk

[1] Medical Research Council Special Report Series No 140 Diet and the Teeth, an Experimental Study Part 1 Dental Structure in Dogs. By May Mellanby Pp. 308+109 plates. (London H.M. Stationery Office, 1930) 17s 6d net.

powder and in the fat remaining between the fibres of the lean meat, but not sufficient to prevent the development of marked rickets and gross defects in dental structure when the fat used contains little or none of this factor

The following influence the structure of the teeth the diet, especially its vitamin D, calcium and phosphorus and cereal content, the rate of growth and previous dietetic history of the animal or its mother and certain environmental conditions Of these the most important is the vitamin D intake

When this work was begun, vitamin D had not been differentiated from vitamin A, many experiments were carried out to determine the distribution amongst foodstuffs of the calcifying factor, in general it was found in foods which were known also to be sources of vitamin A, but certain discrepancies were observed, which in the light of later knowledge are readily explained by the fact that the two vitamins are different entities In some respects the tooth of the dog appears to form a more delicate test for the calcifying vitamin than the rickety rat, differences in potency among a series of vegetable oils being readily observed, thus coconut oil contains a fair quantity, and it is also present in some samples of arachis oil, rapeseed, palm kernel, and cottonseed oils contain little or none, and it is absent from olive and linseed oils and vegetable margarines Certain animal fats form much richer sources, most notably cod liver oil, it is also present in beef-suet and butter, but is absent from lard and hydrogenated animal fats

Calcification of the teeth and jaws is also greatly improved by whole milk and egg yolk, cabbage may have a slight effect, but no calcifying vitamin was detected in carrot, and extensive experiments showed that protein, such as meat protein, caseinogen, eggwhite or legumes, carbohydrate, such as glucose or a diastatic digest of a cereal, lemon juice (as a rich source of vitamin C) and yeast (as a rich source of vitamin B) had no influence in improving the structure of the teeth of puppies on the basal diet

Mammalian liver fat, which contains abundant vitamin A, had little effect on calcification, complementary to this result is the more recent finding that irradiated ergosterol, a source of vitamin D unmixed with vitamin A, exerts an extremely powerful influence upon the calcification of the teeth

Vitamin D was found to be destroyed by prolonged exposure to heat with simultaneous oxygenation of the fat containing it, the actual conditions necessary depending on the fat treated, at the same time some evidence was obtained that harmful products were actually produced by this treatment in cod-liver oil and butter Methylation of cod-liver oil also resulted in considerable destruction

Since the hardness of bones and teeth is due to their content of calcium and phosphorus deposited as inorganic salts in the original organic matrix, it is clear that the diet must contain both these elements if calcification is to proceed normally The experiments of Mrs. Mellanby have indicated, however, that the amount of each present in the diet and the Ca P ratio are of little significance in promoting or hindering calcification as compared with the intake of vitamin D In the rat, on the other hand, rickets cannot be produced unless the Ca P ratio is high In puppies, when vitamin D is abundant in the diet, perfect calcification of the teeth occurs even when the calcium intake is very low, on the other hand, when the vitamin D intake is moderate or low, addition of a calcium salt, such as the carbonate or phosphate, results in definite improvement of calcification Thus butter containing moderate amounts of vitamin D is more effective as a calcifying agent when separated milk is added to the diet, the latter acting as a source of calcium, and butterfat which contains no calcium is less efficient than butter The effect of the addition of calcium depends not only on the absolute vitamin D intake, but also on that relative to the nature of the cereal in the diet

One of the most interesting results obtained in the course of the work is the fact that varying the nature of the cereal in the diet, all other constituents being the same, also varies the degree of calcification of the bones and teeth With oatmeal as the cereal the structure of the teeth is the most defective, with white flour the least, other cereals lie between these two in the potency of their anti-calcifying effect, in order, other preparations of oats, rye, barley, maize, the germ of wheat and maize, wholemeal flour and rice, bran has no influence, whilst rye germ exerts a positive calcifying effect Examination of the various constituents of oatmeal showed that the anti calcifying factor was not the fat or the protein, although it might in part accompany these constituents when extracted, nor was it related to the carbohydrate, nucleic acid, or calcium and phosphorus content, or to the acid base ratio of the cereal Rye germ, as well as ergot of rye, were shown to contain small quantities of vitamin D, after the fat had been extracted from the former, and with it the vitamin, the residue had a definite anti calcifying influence Destruction of this factor occurred on heating the cereal with 1 per cent hydrochloric acid or caustic soda for 1½ hours, heating alone had little effect Malting also resulted in some destruction, provided the germinated cereal was allowed to stand for a few days before consumption

Since the cereal forms the chief energy producing constituent of the diet, varying its amount in the diet varies also the number of calories available, and within limits, the growth rate of the puppy On the same diet more rapidly growing animals have worse calcified teeth than those growing more slowly, hence, to obtain comparable results, it is necessary to limit the food consumption of a series of animals to that of the one with the smallest appetite

Experiments on the influence of environment on tooth calcification indicated that confinement played no part, the important factor in this connexion is exposure to sunshine Similarly, irradiation of the animal by a mercury-vapour lamp resulted in improved calcification, but under the

conditions used was not so effective as adding cod-liver oil to the diet, irradiation of various food materials also improved their calcifying action for example, olive oil, butterfat, oatmeal, and maize germ, due to the production of vitamin D from the ergosterol present in them, as was to be expected, even small amounts of irradiated ergo sterol can give nearly perfect calcification

Vitamin D can be stored in the body, hence offspring from a mother well supplied with it show greater resistance to an imperfect diet than young from a mother kept herself on this diet, evidence was obtained that the mother supplies the young from her own stores when her intake is deficient The structure of a tooth is permanent, so that variations in the diet at different periods will be reflected in variations in its structure, in contra distinction, imperfectly calcified bone will be re absorbed when the diet is improved Improvement of a bad diet will be reflected immediately in improved calcification of the later-formed dentine, but a change from a good to a bad diet will have little immediate effect owing to the avail ability of the body's stores of vitamin D

The work here presented proves convincingly that the structure of the teeth of puppies depends almost entirely upon the intake of vitamin D Even although the diet given was soft and pappy, perfectly formed teeth and well-developed jaws were produced, provided a sufficiency of the vitamin was given Exercise of the jaws appears to depend upon the general health, giving an animal some thing hard to gnaw will not produce well developed jaws when the vitamin intake is low

The application of these results to man and the relationship of structure to dental disease will form the subjects of Parts II and III of Mrs Mellanby's reports Considering that rickets occurs in both man and the dog, it might be expected that diet would have an influence upon the structure of human teeth Caries of the teeth, however, does not occur in the latter, so that a relationship be tween this disease and structure must be deter mined in other animals or in man himself Some evidence of such a relationship has already been published (see, for example, the *British Dental Journal*, 1928, July 15), the final reports will be awaited with interest, owing to the importance of such a conclusion for the prevention of human dental disease

Obituary

Prof Augustine Henry

Augustine Henry was born on July 2, 1857, coming of an old Derry family, and possessing to the full the delightful characteristics of the Irish race He was educated at Queen's College, Galway and Belfast, and was trained as a medical man, being L R C P, Edinburgh He began his career as an attached medical officer of the Chinese Imperial Customs at Shanghai In 1882 he was appointed in this capacity to the Customs Station at Ichang on the Yangtze, where he remained for seven years Here he commenced to interest himself in the flora, following in the footsteps of earlier medical officers in India, such as Wallich, Falconer, Cleghorn, Hooker, etc As with these officers, it was doubtless the medicinal possibilities of the many unknown plants which aroused Henry's interest at the outset Even more than in India, China is the home of the *materia medica*, the great therapeutic value of many bulbs, roots, and leaves of common plants being known to the Chinese The legendary Emperor, Chennung, was, so tradition has it, a great exponent of the medicinal values of plants So keen was this interest that it is said that Chennung had a glass window fitted into the wall of his stomach in order to study the reactions of different plants on the alimentary system! Henry will be remembered in horticultural circles as the introducer of the beautiful *Lilium Henryi* and many other Chinese plants

It was during his sojourn at Ichang that Henry commenced his explorations and investigations into the flora, and thus became the first of a select band of adventurous spirits who investigated the flora of central and western China One predecessor there had been, Robert Fortune, who first went to China in 1842 to collect plants for the Royal Horticultural Society, and afterwards, in 1848, on behalf of the East India Company, introduced the tea plant into India But Fortune's work was carried on in other parts of China Henry's collections were chiefly of dried plants, and he wisely sent those first made to Kew, where they were received by Thiselton Dyer with high appreciation for their examination soon showed that a new flora was being tapped For example, the collections from Hupeh (made in 1888), a botanically unexplored country, were found to contain 500 new species of plants and 20 new genera It was here that Henry came across the flowering tree *Davidia* This is now well known in Great Britain, but the seed was not sent home by Henry Veitch, of Chelsea, sent out E H Wilson, who afterwards became famous for his collecting work, and the latter obtained the seed

After a year's leave at home, where Henry found himself eagerly welcomed in botanical circles, he returned to Shanghai, and was soon transferred to Formosa (which had not then been made over to Japan) During three years spent there he collected assiduously and greatly enriched our knowledge of Formosan plants, publishing later a first account of the flora of Formosa Henry had for some time previously ceased to practise medicine In 1896, Sir Robert Hart transferred him to Mengtse in southern Yunnan In this region he collected extensively, and sent home large collections containing many new species He discovered the wild tea plant whilst exploring the virgin forests in the mountains south of the Red River in south-east Yunnan This plant had not previously been discovered out of Assam He was afterwards stationed at Szemao, where his

inexhaustible energy resulted in collections of equally rare and interesting plants

During his numerous explorations Henry's interest had been aroused in trees and in the forests When he finally returned home in 1900, after having accomplished what would have satisfied many men as a life's work, he therefore determined to study forestry For this purpose, being then forty five years old, he joined the French Forestry School at Nancy, where he passed nearly two years, 1902–3 It was in the latter year that, being on furlough, I accompanied the senior class of that school on a tour of the Vosges and first met Henry, who formed one of the class To those who knew that delightful personality, it will be unnecessary to say that Henry was the life and soul of the party, and his quaint Irishisms and anecdotes, rendered into French with a rich Irish brogue, were an unfailing source of merriment

In connexion with his forest work, Henry will be chiefly remembered for his collaboration with the late H J Elwes in producing the great standard work on "The Trees of Great Britain and Ireland", which was published in parts between 1906 and 1913

It was whilst engaged on this work that Henry was appointed to the first readership in forestry founded in 1907 in the new School of Forestry at Cambridge From that appointment he started a second life's work At Cambridge he was chiefly interested in carrying out breeding experiments connected with trees, chiefly elms, on Mendelian lines—a piece of research work which, for some purposes, may have practical results In 1913, Henry was appointed professor of forestry in the College of Science, Dublin, the chair being afterwards absorbed (in 1926) in the Irish National University In addition to the "Trees of Great Britain" he published "Forests and Trees in Relation to Hygiene", and many papers in the *Kew Bulletin* and other scientific publications His travels, apart from China, in the forests of North America and a considerable portion of Europe, gave him an intimate knowledge of the species of trees of many types, a knowledge which was ever at the disposal of all

Henry had a wide circle of friends in many walks of life, and many will remember the kindly face, great energy, and ever ready humour which rendered so many excursions of the Royal Arboricultural Societies the more enjoyable for his company E P STEBBING

PROF F V THEOBALD

FREDERICK VINCENT THEOBALD died on Thursday, Mar 6, at his residence, Wye Court, Wye, Kent, at sixty-one years of age Though a comparatively young man, he had not had good health for some time, being very susceptible to chills Last Easter he made a marvellous recovery from pneumonia, but it undoubtedly left its mark in the form of a weakened heart Some six weeks ago, when about to leave the house for a much-needed change, he became ill and was ordered to bed He seemed to be progressing satisfactorily when bronchitis set in, and this in his weakened state led to his death

The son of the late J P Theobald of Kingston-upon Thames, Theobald's early days were passed at his home and at St Leonards He then went to St John's College, Cambridge From a very early age he was attracted to all forms of Nature study, and at the early age of eight, with childish enthusiasm, he set himself the task of writing the "Fauna of Sussex" The pages in a boyish hand writing showed such promise that his parents deemed them worthy of binding, and they form an interesting first volume to his many subsequent works

Of Theobald's later entomological work much could be written After taking his degree he became an extension lecturer in economic zoology for the University of Cambridge, but on the opening of the South Eastern Agricultural College in 1894 he gave this up, taking up the post of lecturer in agricultural zoology at Wye

Besides the many reports of economic entomology which have appeared from Theobald's pen, he published 'Agricultural Zoology", a standard text book, and "Insect Pests of Fruit", a large reference work which soon found favour amongst the fruit growers not only of Kent but also of Britain generally About this time he was also engaged upon work on mosquitoes, and having completed his 'Monograph of the Mosquitoes of the World", he turned his attention to the Aphidæ This was some twenty years ago, and although the third and last volume of his monograph on the "Plant Lice or Aphidæ of Great Britain" appeared a year ago, he was still at work upon the group at the time of his death

Among the numerous scientific distinctions which came Theobald's way were the election to honorary membership of the Société nationale d'Acclimatation de France, from which he received the Grande Médaille Isidore Geoffroy Saint Hilaire, Société pour l'Étude Agriculturale Zoologique de Bordeaux, Société de Medicine tropicale de Paris, Association of Economic Entomologists of the United States, and the Royal Horticultural Society of Britain, etc He was made an Officer of the Imperial Ottoman Order of the Osmanieh, he was also a Mary Kingsley medallist (University of Liverpool) and a fellow of the Entomological Society of London, only a few years ago he was presented with the Victoria gold medal of honour of the Royal Horticultural Society He was also an early president of the Society of Economic Biologists, and at one time was vice-principal of the South-Eastern Agricultural College

From 1900 to 1904 Theobald was entrusted with the arrangement of the economic zoology collection at the British Museum and resigned his agricultural zoology professorship in the University of London In 1920 he ceased to hold the post of lecturer at Wye College, devoting his time to advisory and research work under the Ministry of Agriculture, and though this work was primarily for the south-eastern province of England, he had much correspondence from other parts of the world

Theobald was not a collector in the ordinary sense of the word, and was always against the formation of mere collections of dried insects, he got together, however, what is probably the finest collection in existence of insects of economic importance, showing the various stages and damage done by these pests In his work he may at times have appeared too hasty in his summing up of obscure matters and so opened himself to criticism, but in time his critics were usually compelled to come round to his way of thinking

Of a kindly and genial nature, Theobald was always more than ready to help with advice those who came to him for assistance, and the present writer, who had the privilege of being in close touch with him for nineteen years, will always be grateful to him for his ever-ready help He was buried in Wye Churchyard on Monday, Mar 10, being borne from the house by colleagues and students of the College to which he had given so much of his time C A W D

We regret to announce the death in his sixty-second year of Prof Robert Franz Pschorr, which occurred quite unexpectedly on Feb 23 in Munich Prof Pschorr occupied the chair of organic chemistry at the Technical High School in Charlottenburg From the *Chemiker Zeitung* we learn the following particulars of his career Born and educated in Munich, he began the study of chemistry there under Adolph von Baeyer Part of his student course was also spent with Bamberger at Zurich and with Knorr at Jena, where he graduated in 1893 Attracted to Berlin by Emil Fischer, he began there his well known work on the synthesis of derivatives of phenanthrene, which at once established his reputation Thereafter Pschorr's chief interest lay in the investigation of the constitution of the alkaloids derived from phenanthrene Shortly after his arrival in Berlin, Pschorr was appointed to a responsible position in the University Chemical Institute, and in 1914 he was elected to succeed Liebermann at Charlottenburg During his later years he devoted considerable attention to the investigation of coal-tar He interested himself greatly in the student-life of Berlin, and became the first president of the students' hostel at Charlottenburg He was the recipient of many academic honours, and was one of the editors of the *Berichte der deutschen chemischen Gesellschaft*

We regret to announce the following deaths

Prof G A Gibson, emeritus professor of mathematics in the University of Glasgow, aged seventy one years

M Armand Solvay, president of the Société Solvay, and honorary member of the Society of Chemical Industry, who was the son of Ernest Solvay, the pioneer of the ammonia soda process, on Feb 2, aged sixty three years

Dr J W L Spence, who was associated with Rontgen in his early investigation of X rays, and was one of the founders of the Radiological Department of Edinburgh Infirmary, on Mar 15

Sir David Wilson, Bart, honorary treasurer and formerly chairman of directors and convener of the science committee of the Highland and Agricultural Society of Scotland, on Mar 8, aged seventy four years

News and Views.

Mr Richard Inwards, pioneer in mining and related operations in various parts of the world celebrates his ninetieth birthday on April 22, an event the more auspicious in view of his maintenance of personal vigour Born at Houghton Regis and educated at Soulbury, Mr Inwards early engaged in and afterwards adopted as a career mining prospection work, allied also with managerial duties He has reported on mining enterprises in Great Britain, Norway, Portugal, Austria, South America, and Mexico, indeed we think he has an even wider range of countries to his credit Elected president of the Royal Meteorological Society in 1894, Mr Inwards served for two years, his presidential addresses were entitled respectively, "Some Phenomena of the Upper Air", and "Weather Fallacies" He was also author of an interesting paper "Turner's Representations of Lightning", showing that the artist's representations might be placed side by side with photographs of lightning, and would be found to convey faithfully to the mind all that the highest powers of sight can perceive in the phenomena Mr Inwards once wrote regarding popular weather prophets "The stock-in trade of a prophet is of a slender and cheap description He must have an inventive mind, a store of self-confidence, a keen memory for successes, and a prompt forgetfulness of failures" Mr Inwards has been a fellow of the Royal Astronomical Society for many years

Classical education, as a contribution to general culture of the mind, is by no means to be held in small repute by those whose training has directed them into scientific channels of thought We sympathise with the view that everyone, including the scientific worker, has much to learn from the classics, and here we evidently have the support of the Archbishop of York, who discussed the matter in his presidential address to the Classical Association on "The Distinctive Excellencies of Greek and Latin" To look back on to a past age, to examine and to assimilate something of the spirit of the sources of our present day civilisation, is a delight and a profitable recreation such as we could wish all members of the scientific professions to enjoy, for the distinctive excellencies of Greek and Latin are unquestionable In so far as there are schools whence youth passes out into the world primed with scientific facts and figures but ignorant almost of the very existence of ancient civilisations, we would support the claims of the humanities—literature, history, philosophy—to recognition, but we would also remind Dr. Temple that there are places where neither the plea nor the support is necessary, where it is the

scientific spirit that is being stifled in a stuffy atmosphere heavy with the odours of the past Dr Temple goes further than we can follow when he expresses alarm at the non classical educational trend of Great Britain There is nothing to get alarmed about in the spread of an honest search for knowledge, indeed, our feeling of alarm is reserved for the consequences of forgetting that the need of a scientific age is a scientific education

It is all very well to say that except for those who are to be specialists in the study or application of the natural sciences it is more important to know about European civilisation than to know about the solar system, but the inference that the advance of civilisation is not very closely dependent on the progress of science is one which few students of mankind will admit It is no doubt also very true to say that the most important of any human being's relationships are those between himself and his God, and those between himself and his neighbours There is, however, no prohibition of the use of a more strictly theological term to express the scientific worker's 'ultimate cause', no monopoly of a sense of the wonder and power of which no one is more acutely aware than the student of science, whilst as for a man's relations with his neighbours, what better apprenticeship could he serve than that which demands of him exceptional patience and the strictest integrity, and encourages him to regard his fellows as members of an international fraternity? Does he think too highly of his ability, an hour's study of astronomy will convince him of his impotence Is he unaware of the powers that are at his command, chemistry, medicine, engineering will teach him more than will Greek and Latin Let him first learn his own language, learn to love it and learn to use it, then let him turn to foreign tongues, to such foreign tongues as are used to disclose man's mind to day Above all, let him remember that the quest of truth will outlast himself, his generation, even his civilisation, that his dreams, his arts and his literature, however beautiful, may be forgotten a thousand years hence when men are still building on the scientific foundations he has laid to day

Not very long ago the public, or at least that part of it which has any care for the beauties of the country side, was shocked at the ravages of quarrying operations at Malvern A project of a similar nature but even more serious in its consequences is contemplated in Northumberland It will affect five miles of the finest stretch of Hadrian's Wall A company is to be formed to quarry the whinsill dyke in the neighbourhood of Shields-on the-Wall, Pell Crag, and Housesteads The site of the projected quarries includes the finest and most characteristic of the Wall scenery About 200,000 tons of material will be removed annually, and eventually, it is estimated, 100,000,000 tons of whinstone will be taken away Although it is difficult to forecast the ultimate effect of its removal on the land surface, it is certain that the landscape will be completely transformed and the meaning of the Wall utterly obscured The relation to the surrounding country, which determined the siting of the Wall as a defensive work, will vanish with inestimable loss to the study of Roman culture and military science in Britain The Wall will be left on the edge of a high cliff and be quite inaccessible from the south, for in some places quarrying may proceed to a depth of as much as 400 ft The beautiful scenery thus to be obliterated includes land around the fort at Housesteads, the Borcovicus of Roman times, lately presented to the National Trust by Mr J M Clayton

A vigorous resolution of protest has been framed by the Council of the Society of Antiquaries of Newcastle on Tyne, but the proposal is a calamity which calls for nothing less than a national protest The Wall, like Stonehenge, is essentially a characteristic element in the history of British culture The magnitude of the financial interests involved should not be allowed to stand in the way of its safety and it should be saved as Stonehenge was saved in similar circumstances Hadrian's Wall has been scheduled as an 'ancient monument', but the existing law does not allow the surrounding countryside to be protected in this manner In a clash of historical and economic interests of this magnitude, pressure should come from the nation as a whole to secure that commercial considerations should give way and the law be amended to make it possible not only for the country adjoining the Wall and forming an integral part of the ancient line of defence to be declared a national park, but also that legal provisions should be so framed as to make any similar situation impossible in the future

As we have already announced, an exhibition of objects illustrating the culture of Zimbabwe opened in the Assyrian Basement of the British Museum on April 7 Among the chief contributors are the British Museum, the South African Museum of Cape Town, the Rhodesian Museum, Bulawayo, and the Queen Victoria Memorial Museum, Salisbury The recent excavations of Miss Caton Thompson at Zimbabwe and of Mr A L Armstrong at Bambata, preparatory to the visit of the British Association to South Africa, are well represented It is intended that the exhibition should afford material for comparison with objects of a similar character from other parts of Africa Among the most interesting objects shown are those of carved soapstone These include examples of the birds of prey, about two feet high, which originally formed the end ornaments of the perpendicular beams crowning the walls of the elliptical temple Four of these are shown with the stone pedestals of others which are decorated with various linear patterns—herring bone, basketry, chevrons, and lozenges A short soapstone cylinder decorated with 'rosettes' is thought by some to be a symbol of fertility Most remarkable for their decoration are the large flat soapstone trays, almost all of them broken in fragments On the exterior of the raised rims is carving in medium relief Sometimes this imitates the appearance of plaited grass trays of similar shape, sometimes it shows scenes of animal life, especially long horned cattle One of the most remarkable is a hunting scene in which the hunter and his dog, baboons, a bird, and zebra appear This was published in the *Times* of April 7, accompanying an article by Prof J L Myres, in which he summarised the results

of Miss Caton Thompson's work in their bearing on the problem of the origin and date of Zimbabwe

The Minister of Health, Mr Arthur Greenwood, announced in the House of Commons on April 9 that the committee on post graduate medical education, composed of fourteen leading physicians and surgeons appointed by his predecessor, Mr Neville Chamberlain, in July 1925, has issued a report recommending the establishment of a British Post Graduate Hospital and Medical School The possibility of converting the West London Hospital, which does not possess a medical school, had first been considered by the committee, but it was found that the capital cost of conversion and equipment would not be less than £400,000, while the cost of maintenance would be at least £100,000 a year exclusive of the medical school Moreover, the site, covering only 2½ acres, did not allow of any further expansion The hospital finally chosen was the Hammersmith Hospital in Ducane Road, built in 1905, containing 400 beds in modern wards, which was transferred from the now extinct Boards of Guardians to the London County Council on April 1 The hospital will continue to be supported by the rates, and the Government has decided to contribute from the public funds a sum of £250,000 for building and equipping a medical school as well as to provide grants for its maintenance through the University of London An appeal will shortly be made to the public for funds to establish a residential hostel in the centre of London for the use of students of both sexes, not only in medicine but also in other arts and sciences, from the Dominions and Colonies The Committee's report has been published by His Majesty's Stationery Office as a White Paper (*9d* net)

The Radium Commission has issued a statement on the progress of the national organisation which it is engaged in setting up The cardinal feature of the Commission's policy has been the concentration of national radium at a limited number of centres in England, Scotland, and Wales, where there are medical schools with complete clinical courses, and where treatment of patients can be combined with education in approved methods of radium therapy Of these centres 12 have already been nominated, and will be recognised as 'National Radium Centres' as soon as they have complied with the requirements of the Commission They are as follows —Birmingham, Bristol, Leeds, Liverpool, Manchester, Newcastle, Sheffield, Aberdeen, Dundee, Edinburgh, Glasgow, and Cardiff In every instance the channel of communication between the Commission and the centre is the medical faculty of the local university, and loans of radium are being restricted in each area to one hospital selected by the faculty By these means it should prove possible to avoid the dangers and futilities of splitting up the limited national stock of radium into small quantities, which would not only give ineffective results, but also contribute little, if anything, to a national controlled and co ordinated study and practice of radium therapy

London has been treated as a separate and special problem, in view of its position as the metropolis of the whole country Here no centre of the normal type is being set up, but steps have been taken to organise two centres to carry out special work of general and national importance One of these, the Westminster Hospital, has been experimenting, on behalf of the Commission, for several months past with a 'bomb' (containing 4 gm of radium), in order to determine the value of long-distance radium therapy The other London centre which is being organised by the Commission is one for the development of post graduate teaching in radium therapy—a prime and urgent need—and the facilities which will be provided will be available for the benefit of qualified medical practitioners from any part of Great Britain This centre will be located at the Radium Institute and the Mount Vernon Hospital (Northwood), which institutes for these purposes are being reorganised as a joint teaching centre styled the "Mount Vernon and Radium Institute", under a single control, so far as medical services, teaching, and research are concerned

Mr Henry Twitchin, who died at Nice on Mar 19, has left the whole of his property, with the exception of certain minor legacies, to the Eugenics Society The bequest is accompanied by no conditions, except that the capital is to remain intact Mr Twitchin, who came of an English farming family, settled in Western Australia, and came to own two large stations His attention was attracted to eugenics by his own personal experiences as a pastoralist, and probably by a belief that he himself suffered in health from hereditary defects He was, therefore, above all things anxious that eugenists should be practical in their aims, fully believing that we now know enough to advance safely in many directions He had for many years subscribed generously to the Eugenics Society, but insisted on remaining strictly anonymous His aim was to benefit mankind, without winning any notoriety for himself The value of the bequest is not yet known, but it will probably be not very far short of £100,000

An important contribution to the proposals which have recently been made for the reform of the British patent system is furnished in a memorandum issued by a joint chemical committee representing the Association of British Chemical Manufacturers, the Chemical Society, the Faraday Society, the Federal Council for Chemistry, the Institute of Chemistry, the Institution of Chemical Engineers, the Society of Chemical Industry and the Society of Dyers and Colourists The memorandum, like other similar documents of the past year or two, is based upon the report of the Patent Law Reform Committee of the British Science Guild, and is admirably drawn up The proposals are classified into 'major', 'minor', and 'controversial', the latter class comprising those in which the committee differs from the conclusions reached by the British Science Guild A valuable feature of the memorandum lies in the concrete suggestions which it puts forward for the amendment of various sections of the Patents Acts; it is distinctly advantageous to have a definite form of words

as a basis for discussion on such subjects Further, the memorandum supplements the Guild's proposals in respect of some matters, of special interest to chemists, which were somewhat overlooked in the parent report

AMONG the more important of the Joint Chemical Committee's recommendations the following may be mentioned (1) Extension of the Patent Office search to cover a wider field than at present, (2) restriction on the granting of 'selection patents', (3) extension of the Comptroller's judicial powers, by the introduction of a new ground of opposition ('no manner of manufacture'), (4) restrictions on 'user patents' and on unduly wide claims The memorandum does not favour the suggested introduction of 'short term patents' (*Gebrauchsmuster*), on the ground that these would hamper rather than encourage manufacturers The most interesting part of the memorandum, however, is that which deals with medical patents At present, medical ethics precludes the patenting of drugs and biochemical products which are of use in medicine, with the result that foreign patentees are able to exploit British discoveries to their own advantage, while British manufacturers may be deprived of the assurance of such reasonable return on their outlay as would enable them to put new products of high quality on the market at moderate prices The memorandum puts forward in considerable detail a scheme whereby medical patents may be dedicated to the State and administered by a 'Medical Patents Trustee' acting under the guidance of a suitably constituted advisory committee

SEVERAL reports have appeared in the press recently of a communication made on April 9 by Prof W B Harkins to the American Chemical Society, on the effect of collisions between α particles and nitrogen atoms It is not clear from these whether Prof Harkins has been describing new work, or whether he has merely given an account of the earlier researches made on this subject by him, some details of which have already been published In these, the cracks of α particles in nitrogen are observed by the cloud method of Prof C T R Wilson A very small proportion of the collisions between the nuclei of helium and of nitrogen result in the appearance of a new fast proton, and the formation of a fresh, heavy nucleus which is almost certainly that of an isotope of oxygen, since the α particle disappears Excellent photographs of this effect were obtained several years ago by Mr Blackett in the Cavendish Laboratory, and many investigations of it have been made during the last decade by other methods by Sir Ernest Rutherford and Dr Chadwick and others The advantage of the cloud method is that it gives fairly complete information about the fate of all the interacting particles in any particular collision Its great disadvantage is that it is extremely tedious, since reorganisation of the nitrogen nucleus happens so rarely that only about ten cases in which this has occurred have as yet been photographed, although of course many thousands of the protons ejected have been recorded by the method of scintillations and by the use of electrical counters The theory of the effect is now receiving the attention of physicists on the basis of the wave mechanics, and also, whereas it was thought at one time that oxygen was a pure element, it is now known from the evidence of band spectra that it does actually possess isotopes

AN inquiry into the teaching of Empire geography in schools is the subject of a report by the Board of Education (Educational Pamphlets, No 79) The inquiry showed that this aspect of geography is not being neglected in elementary and other schools visited It is stated that there is little evidence of that widespread ignorance in schools in Great Britain of the geography of the British Empire which has been alleged to exist, although there is room for improvement and progress There can be no doubt that most children on leaving school have a reasonable knowledge of the topography of the Empire, and the conditions of life in its different parts They also have some knowledge of the sources of authoritative information and some ability to interpret and apply that information The inquiry has suggested a doubt as to whether too much is not expected of the average child, and it is clear that the time available makes it impossible to give a detailed knowledge of particular parts of the Empire It is noted that the demand for specialists to teach the subject is increasing

THE annual report for the fiscal year ending June 30, 1929, of the Director of the Bureau of Standards (*Miscellaneous Publication*, No 102, Washington, D C Government Printing Office, 10 cents) is interesting and instructive During the past year there has been much correspondence and discussion relative to the question of defining the yard in terms of wave lengths of light The International Conference on Weights and Measures has agreed that the length of the metre is equivalent to 1553164 13 wave lengths of the red radiation from cadmium when produced under standard conditions The Bureau is anxious that the yard should be accepted as equal to 0 9144 metre or, which is the same thing, that the inch should be taken as exactly equal to 2 54 millimetres At the same time, it is highly desirable that industrial measures of length should have their nominal dimensions correct at a temperature of 68° F (20° C) If this were done, then, in the opinion of the Bureau, the problem of the international interchangeability of parts would be completely and satisfactorily solved The search for a source of homogeneous radiation has been renewed Since Michelson compared in 1893 the wave length of the red radiation of cadmium with the length of the international metre, no serious competitor to the red cadmium line has been forthcoming A line of krypton which was very narrow was tried, but proved unsatisfactory, as it lacked intensity and was subject to reversal Certain lines of krypton and xenon might usefully be employed as auxiliary standards, but they compare unfavourably with cadmium red Photo electric cells with a Riefler clock have proved useful for obtaining accurate time signals The signals for distribution to the Bureau's laboratories are correct to about 0 0001 sec

IT is stated in the annual report that the total expenditure of the United States Bureau of Standards for the year 1928–29 was £460,000, about 7 per cent less than the average of the two previous years Salaries amount to £117,000, cost of testing structural materials £45,000, of industrial research £32,000, of commercial aircraft research £25,000, and of research on the standardisation of mechanical appliances £33,000 The fee value of the commercial tests carried out for the State departments and for industry was £109,000 The staff consists of 365 regular members and about a hundred research associate members The average salary is £480 The *Journal of Research* published by the Bureau has now nearly six thousand subscribers

THE Right Hon Sir Samuel Hoare, Secretary of State for Air, 1922–29, has accepted nomination as president of the British Science Guild in succession to the Right Hon Lord Melchett

THE twentieth annual May lecture of the Institute of Metals will be given on Wednesday, May 7, by Major F A Freeth, who will take as his subject " The Influence of Technique on Research "

AT the annual meeting of the Société Nationale d'Acclimatation de France in Paris on April 6, Dr C Tate Regan, F R S , Director of the British Museum (Natural History), received the Isidore Geoffroy Saint-Hilaire medal for 1929

AT the meeting of the London Mathematical Society on May 15, at 5 P M , at Burlington House, Prof G I Taylor will deliver a lecture on " Recent Work on the Flow of Compressible Fluids " Members of other scientific societies who are interested are invited to attend

A ' FREDERICK G DONNAN FELLOWSHIP ' in Chemistry, open to graduates of the universities of Great Britain and Northern Ireland, has been founded at Johns Hopkins University, Baltimore, in honour of Prof Donnan, professor of general chemistry in the University of London Prof Donnan last year had the honorary degree of LL D conferred upon him by the Johns Hopkins University, and also the honorary degree of D Sc by Princeton University and Oberlin College He is to receive the honorary degree of D Sc from the University of Durham in June, and has this year been elected a foreign member of the Royal Society of Sciences, Uppsala

AT the annual meeting on Feb 3 of the Asiatic Society of Bengal, the Barclay Memorial Medal, which is awarded each alternate year to that person who, in the opinion of the Council, has made conspicuously important contributions to medical or biological science with reference to India, was awarded to Mr Albert Howard, director of the Institute of Plant Industry, Indore, and Agricultural Adviser to States in Central India The Joy Gobind Law Memorial Medal, which was instituted last year and is to be awarded every three years to that person who, in the opinion of the Council, has made conspicuously important contributions to our knowledge of zoology in Asia, was awarded to Prof Max Weber, emeritus professor of zoology in the University of Amsterdam, for his contributions to our knowledge of the fauna of Asia as director of the *Siboga* Expedition to the Malay Archipelago, and for his work on Indo-Malayan fishes

A PRELIMINARY programme has been issued of the Portsmouth Congress of the Royal Institute of Public Health to be held on June 4–9 The presidents of the five sections and the subjects of their respective addresses are as follow Prof H R Kenwood, the reduction of preventable diseases (Section I , State medicine and municipal hygiene), Surgeon Rear Admiral H C Whiteside, problems of the sea faring doctor (Section II , naval, military and air, including tropical diseases), Sir Thomas Oliver, the health of the modern worker (Section III , industrial hygiene), Lady Keyes, the voluntary worker in public health service (Section IV , women and children and the public health), Sir Henry Gauvain, sun treatment in England (Section V , tuberculosis) Several discussions have been arranged and numerous papers are promised Particulars of the Congress can be obtained from the secretary of the Institute, 37 Russell Square, London, W C 1

WITH reference to the classified list of Nobel Prize Awards, published in NATURE of April 5, Prof M W Beyerinck, writing from Gorssel, Deventer, Holland, recalls that during the period of Prof van 't Hoff's prime contributions in connexion with the discovery of the laws of chemical dynamics and osmotic pressure in solutions, for which he was awarded the Nobel Prize in Chemistry for 1901 (the first allocated in the section), he was a professor in Amsterdam, and not in Berlin Van 't Hoff was at the University of Amsterdam from 1878 until 1896, and his collected " Études de dynamique chimique " appeared in 1884, and the celebrated paper on " The Laws of Chemical Equilibrium in the Dilute, Gaseous or Dissolved State of Matter " in 1886 He removed to Berlin in 1896, and passed the remainder of his life in Germany hence Germany was his " working domicile at the time of allotment of the prize ", although, of course, Holland was the scene of the fundamental researches for which the prize was awarded It is desirable also to correct here a mistake in classifying under France the award of the Physics Prize for 1909 to Prof Ferdinand Braun (Strasbourg) Dr von Auwers, Berlin-Siemenstadt, writes to point out that in 1909, Strasbourg and its university were German and not French Prof Braun's name should, therefore, have appeared with the prize awards under Germany

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in geology at University College, Grahamstown, South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (April 25) Full-time teachers at the Technical College and Junior Technical School, Horwich, one mainly for science or mathematics in the Junior Technical School for Engineering Subjects in the College , and one for wood and metal work, and mechanical drawing in day and evening classes—The Secretary, Railway Mechanics' Institute, Horwich (April 26) A research student at St Mary's Hospital, Institute of Pathology and Research—The Secretary, Institute of Pathology and Research, St Mary's Hospital, Paddington, W.2

(April 28) A senior lecturer in applied mathematics in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (April 30). A first assistant in the clinical laboratory of the Manchester Royal Infirmary—The General Superintendent and Secretary, Royal Infirmary, Manchester (April 30). A full time assistant master in the Junior Technical School and Evening Technical Classes of the Worsley Technical School, near Manchester—The Secretary for Higher Education, Town Hall, Walkden (May 1). Readers, (a) economics, with special reference to banking and currency, (b) economics, with special reference to industrial organisation, and (c) international history, at the London School of Economics—The Academic Registrar, University of London, S.W.7 (May 1). A technical assistant in the department of the Chief Officer of the London Fire Brigade for inspectorial and advisory duties connected with fire and safety matters in buildings licensed by the London County Council for public entertainment—The Clerk of the London County Council, The County Hall, Westminster Bridge, S.E.1 (May 5). A woman demonstrator in pathology at the London (Royal Free Hospital) School of Medicine for Women and Royal Free Hospital—The Warden and Secretary, 8 Hunter Street, W.C.1, or the Secretary, Royal Free Hospital, W.C.1 (May 6). An assistant medical secretary of the British Medical Association—The Medical Secretary, British Medical Association, Tavistock Square, W.C.1 (May 12). A soil chemist in the department of agriculture, Kenya—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S.W.1 (May 15). A professor of mechanical engineering at the Bengal Engineering College, Sibpur, Bengal—The Secretary to the High Commissioner for India, General Department, India House, Aldwych, W.C.2 (May 19). A laboratory assistant for the medical department of Kenya Colony—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/2117).

Our Astronomical Column

Recent Magnetic Disturbances.—A magnetic disturbance with a range in declination of 30′ was registered at Greenwich between April 6 and 9. There was no definite commencement, which may be taken as occurring about 18h on April 6. The greatest range in declination was registered on April 7–8. This is the third member of a sequence of three small storms which have taken place at intervals of about a solar synodic rotation. The dates of the two preceding storms are Mar. 11–18 (commencement Mar. 11.6) and Feb. 12–16 (commencement Feb. 12.9). No unusual solar disturbance was observed on any of the above dates, but cloudy weather in England rendered observing impossible on most days just before and during each magnetic storm. It may be noted, however, that a fair sized sunspot in latitude 17° N. crossed the sun's central meridian on April 7.1.

Distance of the Trans-Neptunian Planet.—Prof. G. Armellini, Capitol Observatory, Rome, writing with reference to the distance of the Trans-Neptunian planet, reminds us that in 1918 he published in *Scientia* (vol. 24) a simple relation between the distances of the planets from the sun. This relation is given by the formula $D = 1.53^n$, where $n = -2$ for Mercury, -1 for Venus, 0 for the earth, 1 for Mars, etc. For the Trans-Neptunian planet, $D = 1.53^9 = 45.6$. The distance calculated by Bode's law is 77.2, and by Bélot's law (*Comptes rendus*, II. p. 937, 1905) is 61. Prof. Armellini regards the true distance as probably between 45 and 48, and his value agrees with this estimate. We do not, however, know the distance of the new planet yet. Assuming a circular orbit, the distance comes out close to 40, but it is probably an ellipse, and a much longer interval is required to determine its elements.

Photo-electric Observations at Neubabelsberg.—*Astr. Nach.*, No. 5683, contains a paper on these observations by Margarete Gussow. The most interesting of the stars the light changes of which were investigated is Boss 46. This is one of the very massive stars, of type *O*, the radial velocities of which have been studied at the Victoria Observatory. It was found by Prof. Guthnick in 1919 that the star has a small variation of light, the full period of variation is 3.52 days, but this contains two unequal maxima and two minima. A paper by J. A. Pearce in vol. 3 of the Victoria publications discussed both the photometric and spectroscopic data: he showed that the system consisted of two enormous stars, the diameters of which are 23.8 and 15.5 times that of the sun, their masses being 36.3 and 33.8 times the sun's. They revolve nearly in contact with each other, and their shapes differ sensibly from spheres in consequence of tidal distortion, the eclipses are only small partial ones, and would scarcely have been detected without the photo-electric cell, the light range being 0.17 mag. Their detection enables accurate deductions to be made of the masses, diameters, and relative surface brightness of the components. These deductions are of use in making probable assumptions regarding the elements of the Plaskett star, B.D. +6° 1309. This is still more massive, but no eclipses have so far been detected. The light curve of Boss 46 appears to show progressive change since 1919, the two maxima having become more nearly equal; this might be explained by a motion of the line of apsides, which would undoubtedly be present. ζ Geminorum is another of the stars discussed in the paper; the light range is more than 0.6 mag., the period being 10.15 days; the colour index is found to change by 0.2 mag. in the same period, being 0.47 mag. at light maximum, and 0.66 mag. about a day before light minimum. α Canum Ven. was also examined; the observations in 1927 showed a regular light variation in the spectroscopic period of 5.47 days; the light range is less than 0.05 mag.: the variation is less clearly shown in the observations of 1928, 1929.

Annuaire Astronomique et Météorologique Camille Flammarion pour 1930.—This publication (printed by Jouve et Cie, Paris, published by Juvisy Observatory, Seine et Oise, 12 francs) contains all the usual almanac matter relating to the positions of sun, moon, planets, etc., with several other features likely to help amateur observers. There is a very full table of the elements of the periodic comets prepared by M. F. Baldet, also tables of double stars, variable stars, stars of large proper motion, etc. There are also sections on magnetism and meteorology, a table for the date of Easter up to the year 2200 is of course based on the assumption that no change will be made in the method of computation. The hints on choice of a telescope and methods of observing should be helpful to beginners. The work is edited by M. Ernest Flammarion.

Research Items

White Immigrants in Polynesian Tradition.—Mr. W. Ivens, in *Man* for March, discusses a number of traditions relating to white beings which occur in various parts of the Pacific. Malekula, New Hebrides, is said once to have been inhabited by a race called Ambat, who were white, and when Europeans first arrived on the island, they were believed to belong to that race and called by the same name. The Maoris believed in the existence of a white race of *atua*, and on Motu Island, Banks group, Bishop Selwyn and Bishop Patteson were taken for Kwat, the legendary hero: the origin of the association possibly being that he may have been supposed to be white. On North Mala, Solomon Islands, immigrants, white in colour, are said to have arrived in outrigger canoes at a place called Suuna Rii. They wore clothes and coverings to conceal their hair. Their hair was red, but for anyone to see it meant death at their hands. No name is given them, but they are accredited with the introduction of fighting, of magic, and of food plants, including the areca nut. They are worshipped on North Mala as *agalo i mae*, ghosts of war. The head covering of the *agalo i mae* survives in the pigtail of the statues of south-east Solomons, and the carved figures on Vanua Leva, Banks Islands, have a decided pigtail. In the Paumotus and Tahiti there are traditions of red-headed women who rose up from the floor of the lagoon. If, as seems possible, any connexion is to be seen between all these legends, the people to whom they relate may represent a movement into the Pacific at a very early date.

Neolithic Camps.—In *Antiquity* for March, Mr. E. Cecil Curwen, writing on neolithic camps, points out that while the popular attribution of prehistoric hill-forts either to the Stone age or the Roman occupation is usually erroneous, progress in prehistoric research in Britain during the last two decades has justified the popular belief in the existence of neolithic camps, though not in the specific instances expected. Among the neolithic camps described, special importance attaches to the account of Windmill Hill, near Avebury, which is based upon material supplied by Mr. Keiller, by whom the site has been explored annually since 1925, though his own reports are not yet published. The camp consisted of three rings of not quite concentric ditches, in most cases accompanied by ramparts on the inner sides. All these ditches are interrupted by numerous causeways. The outstanding value of this site lies in the stratification of the finds. British neolithic camps have certain very definite features, not all, however, exclusive to that period. Most obvious is the tendency for the ditches to be interrupted by causeways. It is suggested that these may have been intended to enable the defenders to sally forth at frequent points along the line of defence. There is also a tendency to concentric lines of defence with neutral ground between—not exclusively neolithic, but if one of the outer rings is fragmentary the presumption is strengthened. In some cases the defences are deficient altogether where the hill falls away steeply. The ground plan varies, but if one is more common than any it is the oval unrelated to the contour of the ground. The situation varies, the majority being on hill tops—but low-lying sites occur as at Abingdon. Of the hill forts some, curiously, are situated on a saddle between two eminences. In the consideration of the pottery, it is suggested that in the so-called Windmill Hill class two sources of influence are to be discerned, one from Portugal and Brittany, and one from Sweden and Norway.

Mammals of Uruguay.—The report on the collection made by the Captain Marshall Field Expedition during four months in 1926 and 1927 is made the basis of a complete list of Uruguayan land mammals by Colin C. Sanborn (*Field Mus. Nat. Hist.*, Publ. 265, 1929). The introduction mentions that the expedition collected 345 mammals, representing thirty species, but it does not even mention the total number of forms now recorded from Uruguay (they appear to be 53 or 54), and says not a word about the relationship of the mammalian fauna as a whole. We note, however, that three introduced European animals, the house mouse, the Norway rat, and the common hare, have become amongst the commonest and most destructive rodents in Uruguay—another lesson, if one be needed, on the danger of unconsidered importations.

Genetics of Interspecific Hybrid Birds.—Although many interspecific, intergeneric, and interfamilial crosses can be made between gallinaceous birds, such as turkey and guinea fowl, common fowl and guinea fowl, *Gallus bankiva* and *G. varius* and various pheasants, yet the frequent complete sterility of the F_1 prevents further breeding experiments which would determine their genetic composition. Serebrovsky (*Jour. Genetics*, vol. 21, No. 3) shows that it is possible nevertheless to draw important conclusions regarding the genotypic constitution of various species, from a study of the characters shown by the F_1 hybrids in crosses with different breeds of domestic fowls having various dominant or recessive characters which have probably arisen by mutation. From a study of such hybrid specimens in the museums at Hamburg and Berlin, he finds that such factors as bare neck, dominant white, melanism, and leg feathering, which are dominant in crosses between different breeds of fowls, are also dominant in the hybrids between fowls and various other genera of wild Gallinaceæ, Phasianidæ, and Tetraidæ. By the use of this method it should be possible to arrive at definite conclusions concerning the part played by mutations in the process of specific differentiation among these birds.

Dragon-Flies of the Family Cordulegasteridæ.—Owing to post-War difficulties attending the publication of the well-known series of memoirs entitled "Collections Zoologiques du Baron Edm. de Selys Longchamps", the issue of further fascicles of that work has had to remain in abeyance. The parts dealing with the dragon flies were never completed and Lieut.-Col. F. C. Fraser has aimed at their continuation. In *Memoirs of the Indian Museum*, vol. 9, part 3, 1929, pp. 69-167, he has contributed an important revisional monograph of the family Cordulegasteridæ. This paper forms Part 1 of a general revision of the whole group of the Fissilabioidea: its two remaining families, the Petaluridæ and Petaliidæ, it is mentioned, will form the subject of a subsequent contribution by Dr. R. J. Tillyard. The Zoological Survey of India is to be congratulated on having undertaken the work of publication, as a considerable part of the fauna dealt with occurs within the limits of the Indian Empire. The family under consideration comprises four genera and forty-five species and subspecies. These are fully described and figured in the present memoir, which forms a useful and complete account of the insects concerned.

Nutrition of the *Grantia* Amphiblastula.—Prof. J. B. Gatenby and Dr. S. D. King (*Jour. R. Micr. Soc.*,

Dec 1929) state that in well fixed preparations of *Grantia compressa* with amphiblastula larvæ there are near the larva a number of wandering cells, apparently amœbocytes In a later stage these cells become more numerous either by division or by the wandering in of others, and still later these cells form a wall round the amphiblastula Sometimes the wall or sheath is complete, but in other cases there are gaps The cells of this sheath are of two kinds—non granular cells which abut against the flagellated layer of the amphiblastula and granular cells against the posterior granular cells of the larva These latter cells contain osmiophile granules and ' there can be no doubt that these membranes form a sort of placenta between the mother sponge and the larvæ "

Polychæta of Lake Baikal—B Dybowski (*Bull Internat Acad Polon Sci Lettres* Ser B 2 Oct Dec 1929) criticises the memoir of Zenkewitsch (1925) on the fresh water Polychætes of Lake Baikal and dissents from the latter author's view that the fauna is to be regarded as a primitive fresh water fauna The generic characters of the fresh water polychætes *Manayunkia* Leidy, *Haplobranchus* Bourne, and *Dybowscella* Nusbaum are reviewed and two new genera established—*Trichosobranchella* and *Garjaiewella* The last four of these genera are represented each by a single species in Lake Baikal To merge these genera with Manayunkia is undesirable The author recalls with justifiable satisfaction his finding in April 1870 of the trochophore larvæ for the first time in Lake Baikal and adds a few other details of historical interest

Manurial Experiments on Fruit Trees—Mr T Wallace continues the description of these valuable experiments in the *Journal of Pomology*, vol 8, part 1, January 1930 The trees are grown in pots in sand cultures and their behaviour in complete nutrient solutions compared with their behaviour when the nutrient supplied is deficient in either potassium, magnesium, or calcium In this present paper, very full ash analyses of the pruned shoots over a period of three years are given Characteristic effects were produced by the omission of each element Potassium deficiency led to increased shoot growth, leaf scorch, and defoliation of shoots from tip to base Calcium and magnesium omission both led to reduction of shoot growth after the first season and to severe breakdown of leaf tissue The results of magnesium deficiency were especially severe and were reflected in a much lower percentage of dry matter on fresh weight, and thus possibly to a high percentage of ash on dry matter, the calcium and potassium omission series showed a reverse effect—a relatively high dry weight, and low ash content on dry weight Mr Wallace directs attention to the wide variations in the ash constituents in the bark and wood of shoots and main stems The ash is relatively uniform in the bark from both shoot and main stems, but the percentage of ash in the one year shoots is approximately twice as high as in the wood of the four year old stems

Arctic Ice in 1929—The Danish Meteorological Institute has issued the report on the state of the ice in the Arctic seas in 1929 In many respects the distribution was abnormal In the Barents Sea the pack ice was unusually far south in spring, and during April its edge was only 86 miles from the North Cape A few icebergs were close to the Murman coast in May, and throughout the summer, icebergs were seen in the Barents Sea On the west of Spitsbergen there was much ice in May and June In July it decreased, but in August some still remained The east coast was blocked throughout the summer The Spitsbergen ice had a more southern connexion with the east Greenland ice than is usual Along the east coast of Greenland, however, the pack ice formed only a narrow belt, though it extended to Iceland in July and August, there was exceptionally little on the south east coast In Davis Strait and Baffin Bay there was much less ice than usual The Kara Sea was open in August, September, and October The White Sea was blocked with heavy ice until the end of May On the Siberian coast and among the islands of the Canadian Archipelago the conditions were about normal Wrangel Island was accessible in September The report is illustrated with the usual charts and is written in English

Soil Erosion in Tanganyika Territory—Dr E O Teale describes the soil and agricultural development of parts of Northern Kigoma and Southern Bukoba Provinces in *Short Paper* No 4 of the Geological Survey of Tanganyika Territory The questions of soil erosion and conditions for re afforestation are particularly emphasised, for they seriously affect the future prosperity of an otherwise well favoured district The whole of the Kasulu Highlands were formerly covered with forest, but now there are widespread areas of wind swept, torrent cut, and eroded slopes due to the combined application of the axe and annual firing All that was needed to start the rapid disappearance of soil was deforestation Moreover, the custom of farming an area for a few seasons and then deserting it for a new block of virgin land favours the waste that is going on Hillside terracing such as is effectively adopted in southern Europe is not a practicable solution, for there is no local stone and the population is thin Dr Teale shows that, if the future is to be safeguarded, afforestation should be started and maintained by protecting certain selected areas from fire, and headward erosion of streams should be delayed by planting bamboos and native figs at the heads of runnels and gutters which threaten the still unbroken ground of the gentle slopes above them The geological features of the areas considered are described in the paper

Seismic Waves and the Sedimentary Layer—According to T Matuzawa (*Bull Earthquake Research Inst*, Tokyo, Sept 1929, p 257) the crust in the Kwanto district of Japan is made up of three layers (*a*) The upper or granite layer 20 km thick, $Pg = 5\ 0$ km/sec, $Sg = 3\ 15$ km/sec, (*b*) The second or 'intermediate' layer 30 km thick, $P^* = 6\ 2$, $S^* = 3\ 7$, (*c*) The layer immediately below (*b*), 50 km from surface $P = 7\ 5$, $S = 4\ 5$ A Imamura F Kishinouye, and T Kodaira have begun the investigation of the effects of a surface layer of sedimentary rocks overlying the 'granite' layer, basing their work on records of 21 of the 65 moderate shocks that affected the Kwanto district during 1927 (*Bull Earthquake Research Inst*, Tokyo Dec 1929, p 485) Adopting the above data by Matuzawa they find the sedimentary layer to have a thickness of the order 10 km It is not clear, however, that the latter was not already tacitly included in Matuzawa's 'granitic' layer, and until this ambiguity is cleared up the Japanese results remain difficult to interpret

Spectrum of Sodium Hydride—We have received from Prof Takeo Hori, Port Arthur College of Engineering, South Manchuria, a letter describing a band spectrum of sodium hydride which he has obtained in absorption by passing the light from a lamp through sodium vapour heated to 750° C in hydrogen at atmospheric pressure The spectrum between 3680 A and 4450 A was examined in the second order of a

concave grating two metres in radius, and bears a superficial resemblance to the secondary spectrum of hydrogen In spite of its complexity it has, however, been almost completely analysed into seventeen bands, each of which consists of a P branch and an R branch degraded to the red The type of electronic transition involved is ${}^1\Sigma \rightarrow {}^1\Sigma$ An anomaly occurs in the energy of the upper ${}^1\Sigma$ state similar to that found by Nakamura with lithium hydride The moment of inertia of the molecule in the normal state is $5\ 6_4 \times 10^{-40}$ gm cm ^{2}, and the other molecular constants, with the usual notation, $\omega_e'' = 1133$, $B_e'' = 4\ 89_3$, $D_e'' = 3\ 3 \times 10^{-4}$, and $r_e'' = 1\ 9 \times 10^{-8}$ cm

The Nature of Positive Electricity —The first March number of the *Physical Review* contains a letter from J R Oppenheimer, criticising Dr Dirac's theory of positive electricity (see NATURE Feb 1, p 182) Two difficulties occur in connexion with the interaction between radiation and matter applied to this, the theory necessitates the presence of an infinite density of positive electricity, and also predicts that protons and electrons should be equally efficient in scattering soft radiation, whereas it is probable that scattering by protons is relatively unimportant A third difficulty is that, according to Mr Oppenheimer's calculations, the rate of destruction of protons by electrons is far too great The approximate formula for the mean free life (T) of an electron in an enclosure in which there are n free protons per unit volume is $T = m^2c^3e^{-4}n^{-1}$, where e and m are the charge and mass of an electron, and c the velocity of light, which gives a mean free life for ordinary matter of the order of 10^{-10} sec A way of avoiding these difficulties is suggested, but it involves the rejection of the fundamental similarity of positive and negative electricity, which was perhaps the most attractive feature of Dr Dirac's theory, and a return to the hypothesis of two types of independent elementary particles, dissimilar in mass and with opposite charges

Technical Sound Problems —An introductory address on this subject given by Dr E Lubcke of Berlin at the Brunswick Technical School in February, is reproduced in the issue of *Die Naturwissenschaften* for Mar 14 It deals mainly with the use of sound at sea, and in flight, and with the methods suitable for diminishing its propagation in buildings A receiver of the Riegger and Wente type has been used in air, but in water one of the carbon microphone or the condenser type is used The sounds sent out by several types of ship are analysed, and sound spectra are given of a motor boat with its engine making 420 and 600 revolutions per minute, of a tug boat and of a vessel driven by electric motors of high speed The records of an under water explosion are also reproduced, and the method of echoes as used in sounding at sea or from an airship explained In dwellings the oscillations due to traffic are of frequencies 10 25 per second and increase in amplitude from the ground floor upwards to about four times in the first storey and about sixteen times in the second storey that in the ground floor An amplitude of 0 03 mm is already disagreeable, and if due to resonance is reduced by stiffening the floor or wall which is affected In order to prevent sound from penetrating walls, it has been found necessary to use materials weighing at least 150 kgm per square metre of wall

Wireless Defects —In an address to the Institution of Professional Civil Servants, published in the March issue of *State Service*, entitled "What is wrong with Wireless", Mr R A Watson Watt put very clearly before his audience the difficulties which confront broadcast radiotelephony at the present time He considers that the loud speaker, in failing to reproduce in proper proportion the whole of the notes of the musical scale, is the principal offender, the last valve in the average receiver the next, followed by the microphone with its favourite frequencies and its tendency to produce 'blasting' noises during *forte* passages, then the difficulty of spacing out the wavelengths sufficiently when 1000 stations have to be accommodated between wave lengths 100 metres and 2000 metres Lastly, he blames the fading out of signals due to the interference between the direct waves, and those which arrive by reflection in a conducting layer of the atmosphere between 60 miles and 150 miles above the surface of the earth Mr Watt looks forward to the time when these defects will be remedied, but he sees in atmospherics the ultimate limitation on wireless signalling

Building Material and Heat Insulation —Two of the papers read to the International Heating and Ventilating Exhibition at Washington, which are abstracted in a recent *Daily Science News Bulletin* issued by Science Service, Washington, D C, illustrate the advantage of building houses with materials the thermal conductivity of which is low It was found by experiment that a breeze blowing at seven miles per hour and one degree colder than the surface of the building on which it is blowing will carry away by convection three British thermal units of heat from each square foot of surface per hour When the wind is blowing at thirty miles per hour, under the same condition it will carry away eight heat units per hour We may say, roughly, that the heat carried away by convection varies as the square root of the velocity of the wind This law is well known to electricians in connexion with the heating of overhead electric wires The experiments were carried out at the University of Minnesota Further experiments were made on the heating of surfaces by direct radiation from the sun It was found that on an ordinarily bright day in the smoky city of Pittsburg, a piece of black oil cloth ten feet square would receive energy from the sun at the rate of about 45 British thermal units per minute This is equivalent to the oil-cloth receiving energy from the sun at the rate of one horse power If the house is to be kept cool, this shows the necessity of using building materials which are good thermal insulators

Pyrophoric Iron —It has long been known that finely divided iron reacts with incandescence with atmospheric oxygen at room temperature, and several theories have been proposed for the phenomenon In the January number of the *Journal of the American Chemical Society*, T G Finzel describes the preparation of the material, chiefly with the view of investigating the effect of the initial substances used and of various gases on the pyrophoric properties of the iron The iron becomes inactive when heated for some time It was found that the best iron was obtained by the reduction of ferric oxide, precipitated from ferric nitrate, in hydrogen at 500° Chlorides are to be avoided, as they destroy the pyrophoric property of the iron Inactivation depends not only on the temperature and time of heating but also on the gaseous medium One sample became inactive after heating at 600° for 2 5 3 hours in hydrogen, but only after 156 hours in helium, Inactivation appears to be due to decrease in total surface Iron was pyrophoric in dry air and also in air cooled to −78° The adsorption of gases by the material was very irregular, adsorption of carbon dioxide was no criterion for pyrophoric activity Iron prepared from colloidal oxide obtained by hydrolysing ferric nitrate and dialysing was worthless as an ammonia catalyst

High Frequency Fatigue[1]

MESSRS G F Jenkin and G D Lehmann have prepared an important report on the subject of high frequency fatigue These researches, the object of which was to determine the effect of the frequency of alternation of stress on the fatigue limits of various metals, were carried out in the Engineering Laboratories of the University of Oxford, and tests were made on rolled, normalised, and hardened steel, rolled aluminium, annealed copper, and normalised armco iron The ordinary frequency employed in fatigue tests is 50 periods per second though in 1924 Jenkin[2] carried out work up to 2000 periods per second, and in the research described in this paper frequencies up to 20,000 periods per second were used In all the higher frequency tests the specimen consisted of a bar supported at the nodes, and vibrating freely

Jenkin had previously used an electromagnetic method to produce the vibrations, but this will not work for very high frequencies and a new method had to be designed On the experiments now described fluctuations of air pressure acting directly on the specimens were used to make them vibrate The apparatus was essentially two blowers, each blower consisting of a small adjustable resonating chamber, into which air was admitted by a throttle valve in the back, while the front was closed by one face of the specimen The position of the specimen was so arranged that as it vibrated to and fro it alternately released the air pressure or allowed it to mount up in the chamber

The strains were calculated on the assumption that the bar vibrated freely and the only measurement necessary was the amplitude of vibration at the centre of the bar Lord Rayleigh has shown how the strains may be calculated for a long, thin vibrating bar, but using the method of vibrating by air, the bars had to have a moderate width and, for the highest speeds, had to be short, with the result that Lord Rayleigh's theory was no longer sufficiently accurate Prof Love, however, has explained how the theory could be applied to bars of moderate width, such as were used in this apparatus

The results obtained are of very great interest In Jenkin's earlier experiments the largest increase of the fatigue limit observed was only 15 per cent, but, as he pointed out, much larger rises were to be expected at higher frequencies In the present tests, the fatigue limit in all cases increases as the frequency of vibration is raised and increases of fatigue limit up to 60 per cent have been recorded It has also been found that the fatigue limit does not increase indefinitely with the frequency, but apparently reaches a maximum value at a certain critical frequency In some tests it was actually shown to fall at the highest frequencies, the greatest drop obtained beyond the maximum fatigue limit being about 9 per cent of the maximum This fall would probably have occurred for the other metals also, if they had been tested at still higher frequencies The results obtained are summarised in the following table

Material	Critical Frequency (Approx)	Maximum Fatigue Limit (Tons/sq in)	Ratio Maximum F L to Ultimate Tensile Stress	Ratio F L at 50 ~ to Ultimate Tensile Stress	Maximum Increase above F L at 50 ~ (Per cent)
Normalised 0 11 per cent carbon steel	20 000	>17 99	>0 799	0 631	>26 7
Rolled 0 11 per cent carbon steel	>20 000	26 25	>0 588	0 528	>11 5
Annealed copper	10 000	5 50	0 385	0 324	18 8
Rolled aluminium	20 000	5 02	0 785	0 586	33 9
Normalised armco iron	10 000	18 1	0 903	0 685	31 6
Hardened 0 86 per cent carbon steel	10 000	32 4	0 658	0 400	62

South African Vegetation

DURING the recent meeting of the British Association in South Africa, the South African Association for the Advancement of Science may be said to have acted as scientific hosts to their visitors, and in that capacity they certainly spared no effort to provide information as to South African scientific activities which would interest their visitors from the northern hemisphere As a result, the number of the *South African Journal of Science* issued in December 1929, which contains some of the papers read at the 1929 meeting, provides an exceptionally favourable means of gaining a comprehensive impression of South African science The president, Dr Jan H Hofmeyr, in an eloquent address pointed out that, since the first visit of the British Association in 1905, there has been a great increase in the facilities for higher education throughout South Africa, and the 27 graduates of 1905 had increased to 314 in 1928 There has naturally, therefore, been a great amount of valuable scientific work carried out throughout the country since 1905, and Dr Hofmeyr emphasises, as the outstanding feature of this period, that the bulk of this work is due to the activities of South Africans Scientific data are no longer the result of the sporadic activity of visitors from older communities with a longer academic history, they result from the continuous labours of a number of South African investigators, many of whom have received their training in South Africa

Biologically, South Africa is the product of its climate, its sunshine, its clear dry air, and its dependence upon rainfall The remarkable vegetation of this great continent is very much influenced by the very characteristic physical and climatic features of the country, and this report, describing pioneer work in many fields, naturally has to give great space to the tentative generalisations that emerge as to the natural vegetation of the country and as to economic possibilities in agriculture and forestry Prof J H Wellington points out, however, that the three characteristic South African regions, as determined by seasonal precipitation, are equally important in determining human activities These regions are

(1) The western part of Cape Province, with a winter rainfall associated with westerly and north westerly winds from the South Atlantic anticyclone The visiting botanists obtained a slight impression of the possibilities of this type of weather on the occasion of their excursion to the Kirstenbosch Botanic Garden

(2) The vast central and eastern area of the sub

continent, with a summer rainfall, carried to it by the east and north east winds from the anticyclone over the South Indian Ocean

(3) The intermediate region, mainly a coastal strip, on the south and east, where, as a result of its intermediate position, the rains are fairly evenly distributed throughout the year

The high tableland that fills the interior of the continent means that the rain laden winds usually lose their moisture at the mountain barriers near the coast As a result, over a great part of the interior of the continent the rainfall is very scanty, and the deficient moisture supply is the dominant factor determining both natural vegetation and possibilities of cultivation

In the south west of the Cape Province, with its adequate winter rainfall, cultivation is of the type associated with the Mediterranean seaboard Provided there is enough potash, vines may be grown on the alluvial soil, and many visitors will have grateful recollections of the local vintages and the local liqueur Van der Hum The olive, apparently, cannot compete with European conditions for economic rather than climatic reasons But if cultivation problems are somewhat the same, the natural vegetation of the Cape Province is entirely different, for reasons that Dr Marloth makes clear We have in the Cape flora a remarkably diversified vegetation which, in an area about one tenth of the country south of the Orange River, contains as many species as in the remaining nine tenths The bulk of these species are so remarkable in form and so new to the visitor that even the non botanist is led to wonder and admire Dr Marloth lists 64 genera, containing 615 Cape species, which between them include only 19 species that are found outside the Cape region These plants form part of the characteristic southern, sub Antarctic flora, with affinities rather with other Antarctic land masses, and which has remained isolated and distinct by reason of the 'physiological isolation' imposed upon it by the arid tableland that intervenes between it and more northern floras, so that such invasion as does occur takes place either along the more richly endowed coastal strip, or by sea Most of the familiar plants that the visitor first notices, the oaks, the weeds, etc , result from the long history of the Cape as a port of call upon the ocean route to India, before the making of the Suez Canal

Most of the northern immigrants are also unfamiliar to British visitors, being elements identical with, or related to, the main African flora, Acanths, Asclepiads, Euphorbias, etc , and most of the native forest trees , comparatively few familiar northern genera, *Anemone*, *Rubus*, *Hieracium*, etc , are to be seen As a result, the botanist from the northern hemisphere is at first swept off his feet by the vast assembly of striking forms of plants that are new to him , even in the Cape winter the Ericas and Proteas provide him with a wonderful array of flowers , in the spring, the numerous bulbous monocotyledons give sheets of colour on the hillside, and all the year round the flora is full of interest The extraordinarily pronounced development of ericoid vegetation forms at the Cape also strikes the visitor , 21 4 per cent of the flora of French Hoek have ericoid leaves, according to Dr E P Phillips , many of these plants being characteristic of an acid, if not a peaty, soil

Northwards of the Cape, on the high inland plateaux, over many miles of ground, stretches the Karroo, with a rainfall averaging between 3 and 12 inches annually This Karroo vegetation varies greatly in type on the east with a summer rainfall we have a scanty grass veld, merging westwards into the 'Composite' Karroo, grazed by Persian black faced sheep and goats , on the west, with a winter rainfall, the paradise of the succulents, where the more arborescent types predominate until the flora merges into the scrub areas of the coastal belt

Prof R H Compton has a brief note on this interesting vegetation He points out that it is recruited from north and south From the Cape come the leaf succulent Mesembryanths and Crassulas, from the north, stem succulent Euphorbias, Asclepiads, etc , and from the south, geophilous bulbous Monocotyledons, unpalatable Composites, the staple shrubs of the Composite Karroo, and from the igneous outcrops of the Transvaal and Rhodesia come curious plants with 'resurrectionist' habit, etc

Where rainfall is slightly more favourable, the bush savannah or the high veld stretches over many miles of the Transvaal and Rhodesia Dr E P Phillips describes this interesting vegetation in the environs of Pretoria, where high veld and bush veld meet He points out that the tropical element is conspicuous in the bush veld, which shows close affinities with the Kalahari flora

SOUTH AFRICAN FORESTRY

Dr H M Steven has written his impressions of the high forests of South Africa, gained during the British Association tour in 1929, in *Forestry*, vol 3, 1929 The natural high forest in the region of Knysna and George, where rainfall may be expected throughout the year, is a mixed, temperate rain forest type, which in the past has been exploited regardless of the future It is now under the care of a scientific forest service which studies its natural regeneration, but probably no skill could make this natural forest, with its superabundance of hardwood species, and relatively slow increment growth, an economic asset It remains a national asset, and is well worth the care it receives, but South Africa is concerned with the fact that it exports its fruit in boxes made of imported timber and is rapidly introducing exotic softwoods to meet the needs of the industries of the Union Messrs G A Zahn and E J Neethling give an account of progress to date along these lines *Pinus pinaster* has been planted most extensively in the past, but *P insignis* and *P canariensis* now stand higher in favour and are being planted very extensively The yield of wood is already sufficient to enable Mr M H Scott to give some preliminary notes upon the behaviour of the timber of such exotic conifers, whilst the high moisture contents recorded by Mr Nils B Eckbo (for example, 474 per cent on dry weight in the sapwood of *Cryptomeria japonica*) are a reminder that these studies deal as yet with very young grown timber

A new industry of considerable importance has sprung up around the cultivation of the introduced black wattle, *Acacia mollissima*, from which bark and tannin extract are exported annually to the value of about one million pounds Mr A J O'Connor and Dr I J Craib deal with its sylviculture, whilst it would appear, from Mr E F English's account, that most preliminary experiments on paper pulp production from South African hardwoods have been carried out upon the wood of the black wattle With the tree grown especially for bark, a use for the timber is obviously an urgent economic problem

It is interesting to note, with the distribution of the natural forest, and in the problem of plantation management, the dominant external factor in South African conditions is again the water supply Indeed, Dr I J Craib argues, on the basis of his experience gained at the Yale Forestry School, that the moisture content of the soil is in general of more importance than light in forest growth and in controlling the succession of events beneath the forest canopy, that go so far to determine the stability of forest conditions

Dr Craib's discussion of this problem has very general biological interest, as, indeed, do many of the contributions in this issue of *Forestry*, which seem primarily of economic interest

Another very interesting ecological problem is the way in which the diversified native flora is sometimes superseded, as the result of fire or over grazing, by almost pure stands of some particular plant Mrs Levyns gives a brief account of her extensive observations upon one such case, the extensive spread of the rhenoster bush, *Elytropappus rhinocerotis*, which has displaced pasture on the veld under such conditions She shows that the seedlings of this plant flourish when germinating in completely exposed sites where many competitors wither and die, and that germination of the seeds may be better after exposure to a fire—observations which may explain the spread of this plant, which is useless as pasture Sometimes the plants that oust the varied native flora are aliens, as several species of *Hakea* that cover the slopes of Table Mountain after fires

Grasslands

South Africa is now grazed much more closely by the stock of the settlers than was previously the case when wild game alone roamed in the veld For many miles, in the dry South African winter, the only fruiting grass haulms seen from the railway will lie inside the wire fence that protects the rail track from the stock Outside this fence, every palatable plant is grazed ruthlessly down to soil level, and only plants with conspicuous powers of regeneration are able to survive the onslaught The control of grazing so that future resources are not needlessly impoverished, is probably the line of surest advance in many agricultural problems, and the doyen of American agrostologists, Prof A S Hitchcock, of the Smithsonian Institution, has a brief paper upon the relation of grasses to man, which, whilst it emphasises the great importance of these plants is full of wise counsel as to the conservation of grazing land based upon the experience of the United States, where over grazing with the consequent depletion of the range has been a pressing problem, as indeed it has always been in the history of stock raising on open grassland since the days of Abraham

The paper by Messrs R R Staples and A J Taylor upon pasture management shows that South Africa is already attacking its own problems in this field They show that frequent clipping on the veld, to simulate close grazing, materially affects the normal grass flora, both the dominant species, *Themeda triandra* and the coarse pioneer grass, *Eragrostis alba*, succumbing very early under such treatment, whilst an introduced pasture grass, *Paspalum dilatatum*, survived the treatment much better One of the most important results so far obtained in grassland management is undoubtedly the dominant significance of phosphate deficiency in most South African soils Dr I de V Malherbe states that phosphate treatment of arable soils practically always gives a large increase in yield and Dr P J du Toit emphasises the fact that phosphate manuring of grasslands in the form of bone meal has revolutionised the cattle industry in certain parts of South Africa He suggests that, with a small daily ration of the missing mineral, it should be possible to raise improved breeds of cattle on the veld A number of other very interesting contributions, dealing with both the native fauna, the stock and the economically important pests of the cultivator, are also included in this Report of the 27th Annual Meeting of the South African Association", in this review it has been possible to mention only very cursorily some of the many contributions that deal mainly with South African vegetation under both natural and cultivated conditions

Weather and Climate of the Sahara

OUTSIDE the polar regions there is no extensive area of land the weather and climate of which has been so little studied as that of the Sahara, with the possible exception of Central Asia A certain romantic glamour seems to attach itself in the minds of most of us to that vast and little known desert region, and this gives additional interest to a memoir published by the Meteorological Office, Air Ministry (Geophysical Memoir No 48), which discusses in detail the meteorological observations made by Mr Francis Rennell Rodd in 1922 and 1927 in various parts of the Southern Sahara ranging from Timbuktu in the west nearly to Lake Chad in the east, and in latitude from about 12° N to 20° N

This is a region that owes its rainfall to a brief monsoonal incursion of south westerly winds from the southern Atlantic during the late summer These winds penetrate underneath the prevailing easterly or north easterly winds, probably to a height of about 1 kilometre, and the rainfall appears to be generally of a vigorous convectional type, the convection apparently mixes the opposing wind currents and often leaves the easterly wind in temporary occupation of even the lowest layers Occasionally this process gives rise to 'tornadoes' of the African type, which are of the nature of line squalls, not destructive vortices like American tornadoes, they give severe gales of short duration The rainy season appears to be a complicated affair, interrupted by various breaks There was an important autumnal part until about fifteen years ago according to the natives, and Mr Rodd experienced a cloudy spell in late November and early December that yielded a few drops of rain and lent colour to the local tradition He was not of the opinion that any important general desiccation of this part of Africa has been in progress either recently or during past ages

As in many other parts of Africa, the more mountainous districts tend to get abundant rain, while the relatively low lying plains not only have, on an average, a very small annual fall, amounting locally to less than five inches, but also one that is capricious, and in large areas a scanty desert vegetation is only precariously maintained

It is not in regard to rainfall, however, that the interior regions of the Sahara yield the most interesting weather, but in the matter of low relative humidity and the temperature contrasts that arise from it Unfortunately, the degree of dryness experienced when easterly or north easterly winds hold sway is too great for trustworthy treatment by normal hygrometry, and it would be necessary to make special direct absolute determinations to measure accurately the minute fraction of possible water vapour pressure contained by the air on those days when temperature rises to 114°, as happened in June 1922 and September 1927 Some idea was obtained by assuming that the vapour pressure remained constant between the cool early morning, when measurements by ordinary means could be relied on, and the time of greatest heat at 3 P M, so that the relative humidity was governed by air temperature alone There was reason for believing such an assumption to be nearly true, more than one calculation

indicated a relative humidity of only five per cent, with a probability that two per cent may be attained at times

The diurnal range of temperature is so great that, in spite of the very high day temperatures, frost is not unknown On Dec 14, 1922, the air temperature measured on a march by sling thermometer was 92° at 2 30 P M, and during the ensuing night in camp the minimum was 31°

University and Educational Intelligence

London —A Bayliss Starling Memorial Scholarship has been founded by old students, friends, and admirers in commemoration of the late Sir William Bayliss and Prof E H Starling The annual value of the scholarship is about £120, with exemption from tuition fees, and it is tenable at University College The Scholar will be required to follow a course of study approved by the Jodrell professor of physiology, involving a training in the principles of, and methods of research in, physiology and biochemistry Candidates must send their applications to the Secretary of University College not later than Wednesday, May 14

An election of junior Beit fellows for medical research will take place in July next The yearly value of each fellowship will be £400, and the tenure, ordinarily, three years Forms of application (returnable on or before June 1) may be obtained by letter only, addressed to Sir James K Fowler, Honorary Secretary, Beit Memorial Fellowships for Medical Research, 35 Clarges Street, W 1

Applications are invited from British subjects by the L C C for two Robert Blair fellowships in applied science and technology, each of the value of £450 and tenable for one year in the Dominions, the United States, or other places abroad Particulars and application forms (T3/300) are to be had on application to the Education Officer (T 3), The County Hall, S E 1 The latest date for the return of forms is June 18

University College, London, has just issued its report for the year ending February 1930, with statistics for 1928-29 showing a total enrolment of 3249 students, including 2399 whose homes were in the British Isles, 311 from the rest of the Empire, 52 from the United States of America and 487 from other parts of the world 1466 were in the different stages of degree courses, 523 were graduate and research students, 441 evening and 266 vacation students In addition, free public lectures, among them seven by visiting professors from the continent—Dutch (2), Belgian, German (2), Swedish, and Danish universities—were attended by more than 14,450 persons, the aggregate number of attendances at the 67 lectures being 29,590 Among academic developments during the year was the establishment of a chair of American history for which the Commonwealth Fund of New York gave 214,500 dollars The Centenary Fund, inaugurated three years ago to provide £500,000 for the completion of buildings and equipment and for endowment, amounted on Jan 31, 1930, to £223,860 The office of Provost of the College, held for twenty-five years by Sir Gregory Foster, on whom the honour of a baronetcy was conferred last New Year's Day, passed, as from the same date, to Mr Allen Mawer, formerly Baines professor of the English language in the University of Liverpool

Historic Natural Events.

April 20, 1897 Aurora Australis—A remarkable display of aurora was observed in the South Indian Ocean in lat 47½° S It began at 6 30 P M with a diffused light, horizontal flashes soon spread and flared in every direction, increasing in length and brilliancy, until at 7 30 P M they were shooting across the sky to within 30° of the northern horizon Cones and circles of light travelled rapidly over the whole sky, flashing beams of intense brilliancy from one to the other This continued until 8 30 P M, when an arch of bright green light fading off into yellow formed over the southern horizon, rose rapidly to a high altitude, and was followed by similar arches in regular sequence, until there were six distinct arches, their apices being from 10° above the southern horizon to 60° above the northern horizon They were formed of narrow vertical bands of light from 5° to 20° deep, bright green and yellow at their upper edges, and of a rosy hue at their bases At 9 P M a brilliant circle formed round the zenith, composed of narrow bands of light, pendant overhead and having a rotary motion, producing the effect of the vertex of an electrical cyclone The display lasted until 9 45 P M

April 22–25, 1547 Red Sun—In the whole of Germany, France, and England the sun appeared reddish and dull, like a ball with spots, so that the stars were visible (especially on April 24, during the battle of Muhlberg)

April 22, 1884 Colchester Earthquake—No British earthquake has resulted in so much damage to property as this shock Within an area of 10 sq miles to the south and east of Colchester, 1213 buildings and 31 churches had to be repaired In Colchester more than 400 buildings were injured, while at three villages—Abberton, Peldon, and Wivenhoe—about 70 per cent of the chimneys were thrown down The Colchester earthquake is one of the few British earthquakes that have been felt on the Continent, as at Boulogne and Ostend

April 24, 1579 Snow—Holinshed records that snow fell in London between 4 A M and 9 A M to the depth of a foot This is the more remarkable because, according to the present calendar, the date would have been early in May

April 25-26, 1908 Great Snowfall—This was one of the greatest spring snowfalls on record in the Midlands and southern England About six inches of snow fell near London on April 24, but the heaviest fall occurred on April 25, accompanied by a strong gale in the English Channel At Southampton, work at the docks was brought to a standstill, and throughout Oxfordshire, Berkshire, and the north of Hampshire all traffic by road was held up and communication by rail was maintained only with the greatest difficulty The thaw caused a severe flood in the Thames

April 25, 1926 Floods—Owing to a rapid thaw of the heavy snows of the preceding winter, the rivers of Russia were in flood, all the low lying parts of Leningrad, Moscow, and many other towns being under water The damage was accentuated by blocks of drifting ice

April 26–28, 1867 Gale and Floods in Brisbane—Rain commenced to fall on April 26 and continued throughout April 27, becoming torrential on April 28 On this day the wind rose to gale force, doing much damage The river rose rapidly to an abnormally high level, and the banks were covered by debris from the valley The lower parts of Brisbane were flooded

April 26, 1902 Green Flash—Mr C T Whittmell records in the Journal of the British Astronomical

Association that "In the belfry of the Wesleyan Chapel, on the west side of Woodhouse Moor, there are narrow, horizontal openings through which the setting sun can send his rays On Saturday, 26th April, between 7 15 and 7 30 P M I was so exceptionally fortunate as to observe, through the openings, no fewer than three green and red flashes The red ones were seen just as the base of the sun successively revealed itself below each of the upper edges of three openings The green ones were seen just as the top of the sun disappeared behind each of the lower edges of the openings Moving aside afterwards, in order to watch the actual sunset on the true horizon, distant some three miles, I observed a beautiful bluish green flash just as the sun's top sank out of sight at 7h 23m The sky was singularly clear, and there was a cool fresh breeze from north east "

April 26–29, 1928 Dust Fall —A great fall of dust took place in eastern Europe, travelling in a west north west direction from the coast near the Sea of Azov, as far as the upper Weichsel The darkness was so great that artificial light was in use all day, and in southern Russia the fallen dust formed heaps like snow drifts a foot or more in depth, but farther to the north west the depth was less than a sixth of an inch The origin of the dust is unknown, but it occurred with an easterly wind, and was heaviest where this wind reached the coast from the open sea

Societies and Academies

London

Linnean Society, Mar 20 —**C Tate Regan** A new Ceratioid fish (*Caulophryne* sp), female with male, from off Madeira The fish represents a new species of the genus *Caulophryne*, distinguished from *C jordani* Goode and Bean by the greater number of dorsal and anal rays and by the filaments on the stem of the illicium Although distended by a recently swallowed fish larger than itself, it took a bait, and was caught on a long line off Madeira The specimen is a female, 210 (145 + 65) mm long, with a dwarfed and parasitic male 21 (16 + 5) mm long attached to its abdomen —**Lieut -Colonel J Stephenson** On an Oligochæte worm parasitic in frogs of the genus *Phrynomerus* A specimen of a Nigerian frog, *Phrynomerus microps*, recently examined had a number of small worms hanging out in a cluster of about a dozen from the anterior angle of each eye and from under the neighbouring part of the lower lid The worms belonged to a new species of the genus *Nais* of the freshwater family Naididæ In a second species of the genus *Phrynomerus* (*bifasciatus*), from Beira, Portuguese East Africa, the Harderian (lacrymal) glands were found to be distended and transformed into a sac containing a number of small worms , these belonged to the same species as the preceding This discovery prompted the stripping of the mucous membrane from the roof of the mouth of the first frog, from Nigeria, when it was discovered that in it also the Harderian glands contained a number of the worms Oligochæta are rare as external, and still rarer as internal parasites

Society of Public Analysts, April 2 —**Ella M Collin** The separation of cadmium and copper in spelter and zinc ores by internal electrolysis The most satisfactory method is to deposit the copper first from a sulphate solution containing a small excess of sulphuric acid, to dissolve the copper in excess of nitric acid, and to electrolyse the solution at 70° The original sulphate solution is readjusted with ammonia, sulphuric acid, and sodium acetate, and the cadmium electrolytically deposited The anodes are of zinc, and a 5 per cent solution of zinc sulphate acidified with sulphuric acid is used in the anode compartments —**A F Lerrigo** Routine detection of nitrates in milk A modification of the diphenylamine test is capable of detecting the addition of 5 per cent of a water containing about 0 5 part of nitric nitrogen per 100,000 The test is regularly applied in Birmingham to all samples of milk containing less than 8 5 per cent of solids not fat —**J C Ghosh** The determination of titanium as phosphate The prepared ore or clay is fused with sodium carbonate, and the mass treated with boiling water, which dissolves aluminium and silica as sodium salts, leaving sodium titanate in the residue This is hydrolysed and is then dissolved in either sulphuric or hydrochloric acid and when boiled yields a precipitate of metatitanic acid This is dissolved the solution just neutralised with ammonia, and the titanium precipitated and weighed as phosphate

Leeds

Philosophical and Literary Society, Mar 4 —**J E Roberts** Note on the critical potentials of the hydrogen molecule The observed critical potentials of the hydrogen molecule are considered in the light of the potential energy curves for the various states and the Franck Condon principle The most probable energy change requires 12 8 volts, though this is not, strictly speaking a critical potential, the latter being in the region of 12 volts A further potential between 8 and 9 volts reported by Jones and Whiddington is probably due to the excitation of the triplet states with consequent dissociation of the molecule and emission of the continuous spectrum – **J E Roberts and R Whiddington** The passage of electrons through argon Excitation potentials of argon have been investigated experimentally by the magnetic spectrum method already described The three sharp loss lines have been examined photometrically, and found to be much narrower than the corresponding loss lines in the case of certain diatomic molecules In order of intensity, the losses in volts of the lines are 11 6, 14 1, 13 0, and this is the descending order of their intensities —**E C Stoner** (1) Free electrons and ferromagnetism The question is considered as to whether ferromagnetism may be due to 'free electrons', that is, electrons forming an 'electron gas' as in Sommerfield's theory of conductivity For spontaneous magnetisation to occur, the change in the interaction energy associated with magnetisation must exceed the increase in the kinetic energy of the electrons On this basis, it is shown that the Curie temperature θ would have a minimum value depending on the saturation intensity I_0 To a sufficient approximation $\theta > 6\ 74 \times 10^{5} \times I_0^{2/3}$ This gives $\theta > 43{,}160°$ for nickel (observed 640°) and correspondingly large values for other ferromagnetics It is concluded that ferromagnetism is not due to free electrons, but to interchange interaction electrons as in Hasenberg's theory If the 'magnetic' electrons are the same as the conduction electrons, as Dorfmann's thermo electric measurements indicate, it follows that conductivity may be due to interchange electrons The bearing of this on the theory of the magnetic and electric properties of metals is indicated (2) The interchange interaction theory of ferromagnetism Considering the atoms in a crystal as separate systems interacting with neighbouring atoms, a very simple treatment of the interchange interaction theory of ferromagnetism is given The method differs from that of Heisenberg, who considers the whole crystal as a single system The terms which make the original formulæ unsatisfactory

as a representation of the experimental results do not appear The final expressions of the magnetisation energy are formally equivalent to those given by the Weiss theory, if the classical assumption of continuous orientations of the carriers is appropriately modified The agreement with the observations on ferromagnetics is very satisfactory —**H Burton** Mobile anion tautomerism (Pt 5) γ phenyl α p-dimethyl amino phenylallyl alcohol Attempts to prepare the above alcohol have resulted in the formation of a mixture of products, which on treatment with hydrochloric acid furnishes a crimson coloration The cause of the colour is discussed —**E Cockerham** Some observations on cambial activity and seasonal changes in starch content of sycamore (*Acer Pseudoplatanus*) The activity of the cambium in producing both xylem and phloem has been followed throughout the year in all parts of the stem and root of *Acer Pseudoplatanus* Cambial activity is found to initiate in the buds in the spring, and from thence to work basipetally downwards on to the main roots In the distal region in the root this seasonal activity is thus superimposed upon a very slow cambial activity which seems to be practically continuous in this region of the root Fluctuations in starch content are discussed in relation to these data —**H L Newby** and **W H Pearsall** Observations on nitrogen metabolism in the leaves of *Vitis* and *Rheum* Ratio of protein to soluble nitrogen changes with the age of the leaf, and increases when the water content of the leaf is caused to fall The diurnal fluctuations in this ratio are correlated with changes in acidity, increases in acidity being associated with increases of the proportion of protein —**Rosa M Tupper-Carey** Observations on the anatomical changes in tissue bridges across rings through the phloem in trees In a zigzag bridge of phloem left across a ring upon a tree, the new xylem and phloem in the horizontal portion of the bridge is eventually formed with its elements extended in a horizontal direction The developmental changes in the cambium are followed in detail, which bring about this alteration in direction of the elements which differentiate from the cambium —**R G S Hudson** The age of the *Lithostrotion arachnoideum* fauna of the Craven Lowlands The recorded horizons of the various species of the *L arachnoideum* fauna are noted, and the faunal assemblage is considered to be of S_2 age The bearing of this determination on the age of the Clitheroe Pendle succession is discussed Various Lithostrotions are also re described

PARIS

Academy of Sciences, Mar 10 —The president announced the death of Camille Viguier, *Correspondant* for the Section of Anatomy and Zoology —**A Cotton** and **G Dupouy** Measurements of magnetic double refraction with the large Bellevue electromagnet Details of the methods employed for determining the field strength, and of the apparatus used in the optical measurements —**Lucien Daniel** was elected *Correspondant* for the Section of Botany —**Paul Lévy** The probability and the asymptotic frequency of the different values of the complete and incomplete quotients of a continued fraction —**Elie Cartan** The linear representations of the group of rotations of the sphere —**Georges Giraud** Certain problems at the limits concerning equations of the elliptic type —**Paul Flamant** The reduction and the independence of the conditions imposed on families of abstract vectors —**Georges Valiron** Integral functions defined by a class of Dirichlet series —**P Dupin** and **M Teissié-Solier** The distribution of the pressures round an immersed cylinder An experimental study of the distribution of the pressures on a cylinder immersed in a current of water, the results in non-turbulent flow being compared with those obtained with turbulent flow —**Alex Véronnet** The displacement of the poles and the deviation of the continents —**Corps** The interpretation of the Sagnac and Michelson experiments —**Henri Mineur** The field of gravitation of a variable mass —**F Joliot** The electrical properties and the structure of the metallic films obtained by thermal and cathodic projection A study of the causes of the resistance changes in these films the presence of occluded gas, slowing down the recrystallisation of the metal, would appear to be the principal cause of the diminution of electrical resistance —**H Pélabon** The copper oxide rectifier The results are given of a study by metallographic methods of a copper oxide–copper rectifier —**D Chalonge** and **Ny Tsi Zé** The variations of the continuous spectrum of the hydrogen molecule with the conditions of excitation —**G Déjardin** and **R Ricard** The first spark spectrum of mercury (Hg II) —**A Smits** and **Mlle C H Macgillavry** Remarks on the note of Mlle Maracineanu The authors have not verified the results of Mlle Maracineanu in all respects, but only so far as concerns the measurements relating to the radioactivity of lead from the roof of the Paris Observatory Details of a very sensitive method for detecting traces of mercury in lead are given —**H Deslandres** Remarks on the preceding communication —**Pierre Poulenc** The alkaline bromo salts of rhodium —**Marcel Godchot** and **Mlle G Cauquil** The methylcycloheptanols Details of the properties of three alcohols obtained by the reduction of the two methyl cycloheptanones described in an earlier communication —**R Cornubert** and **R Humeau** An ultimate property of the carbonyl group It has been shown that the ketone γ-methyl αα′ tetrapropylcyclohexanone gives neither an oxime, phenylhydrazone, nor tertiary alcohol with magnesium methyl iodide, and can only be characterised by reduction to the secondary alcohol and transformation into the acetate Another ketone, β methyl αα′ tetrapropylcyclohexanone, has now been found to possess similar abnormal properties, but this also can be converted by reduction into the secondary alcohol —**Léon Piaux** Some quaternary iodides derived from phenylaminoacetic acid and the corresponding betaines —**O Munerati** Observations on the duration of the cycle of the beet root —**H Bierry** Glycogen, glucidic reserves, in the starving animal —**Mlle G Cousin** The diapause of *Lucilia sericata* Experiments on *L sericata* have given results at variance with the views of Roubaud The diapause (arrest of larval evolution) can always be traced to external conditions —**H Colin** and **E Guéguen** The sugar of the Floridæ The sugar of the marine Floridæ is a compound of α galactose and has nothing in common with trehalose —**M Javillier** and **Mlle L Emerique** The vitamin activity of carotene Crude carotene, arising from leaves of spinach, has the physiological property of vitamin A It is active in very small doses, less than 0 01 mgm per day The activity of carotene remains high after keeping for forty years It still remains an open question whether the physiological effects of carotene are due to the substance itself or to some adsorbed substance —**A Leulier** and **L Revol** The distribution of cholesterol and its esters in the suprarenal capsules —**J Nicolas** Ulcerated X ray epithelioma cured by diathermocoagulation

PRAGUE

Czech (Bohemian) Academy of Sciences and Arts (Second Class, Natural Science and Medicine), Jan. 10 —**J. Milbauer**: Studies in the preparation of vege

table charcoal (1) The action of calcium chloride as activator The decolorising power of charcoal depends on the tissue of the initial material and the temperature and duration of burning The best material is that with a great content of celulose —**M Mikan** Cremona correspondence in quadridimensional space given by four correlations —**V Spaček** Complex swings of the magnetic declination needle —**E Votoček and F Valentin** Studies in the series of rhodeose (*d*-galacto methylose) —**E Votoček and V Kučerenko** Studies in the series of fucose (*l* galacto-methylose) In both the above communications the optical rotation of the derivatives of rhodeose, epirhodeose, fucose, epifucose are studied and an entire agreement is found with the Hudson's rule, this confirms Hudson's rule also in the series of methyl pentoses —**V Pospíšil** Experimental studies on the pressure effect of light upon microscopic particles —**O Michal** The *K* absorption and the satellites of the ferromagnetic elements The wave length of the *K* absorption edge is negligibly affected, when varying the crystalline diffraction grating —**J Klíma** The construction of flecnoidal lines on the skew planes of fourth order —**F Herles** The significance of the segment *RT* and of the wave *T* in the electrocardiogram for the diagnosis of pathological changes in the myocardium

WASHINGTON, D C

National Academy of Sciences (Proc, Vol 15, No 12, Dec 15, 1929) —**Chas W Metz and M Louise Schmuck** (1) Unisexual progenies and the sex chromosome mechanism in *Sciara* It has been shown previously that sex of individual depends on the sperm, but the types of sperm functioning depend on the zygotic constitution of the female Both characteristics are determined by the sex chromosomes, of which there appear to be three kinds —(2) Further studies on the chromosome mechanism responsible for unisexual progenies in unisexual progenies in *Sciara* Tests of 'exceptional' males Such individuals, to be expected on the hypothesis put forward above, were found —**M Demerec** Changes in the rate of mutability of the mutable miniature gene of *Drosophila virilis* The lines of mutable miniature are described and the rate of change from one to the other determined —**L J Stadler** Chromosome number and the mutation rate in *Avena* and *Triticum* Cultivated oats and wheat are polyploid forms and treatment with X rays produces very few mutants, as judged by seedling characters, in contrast with cultivated barley (normal chromosome content) in which many mutants are produced This appears to be connected with reduplication of chromosomes in polyploid species —**Donald A Johansen** A proposed phylogeny of the Onagraceæ based primarily on number of chromosomes —**Delmer C Cooper** The chromosomes of *Bugainvillæa* —**Robert F Weill** New results from the study of cœlenterate nematocysts (preliminary note) A comprehensive study of nematocysts from 109 species has been made, the nematocysts are of taxonomic value —**Harold Osterberg** An interferometer method of observing the vibrations of an oscillating quartz plate One mirror of the interferometer is replaced by the crystal, which is mounted so that reflection occurs at the surface to be examined —**Jenny F Rosenthal and F A Jenkins** Perturbations in band spectra (2) Perturbations in the Angström bands of carbon monoxide are discussed —**Marie J Weiss** On groups defined by $A^q = 1$, $B^{-1}AB = A^a$, $B^q = A^t$ —**Tracy Yerkes Thomas**: On the existence of integrals of Einstein's gravitational equations for free space and their extension to *n* variables.

The Medical Profession in India

A NUMBER of pamphlets have recently been received at the offices of NATURE, in which are put forth the views of the Indian Medical Association and of certain of its officers on some questions of current medical interest in India The Association holds an annual meeting, the 'All-India Medical Conference', the sixth of these took place in Lahore on Dec 27–28, 1929 Three of the pamphlets relate to this meeting, and contain respectively the addresses of the president and chairman of the Reception Committee, and the resolutions passed at the conference No scientific or medical papers were read, the objects of the conference being rather political or medico political

The president's speech opened with a short discussion of the limits of the membership of the Association, it appears that the rule is to admit practitioners "who have such medical qualifications as may be from time to time recognised by the Association suitable for such membership", and the question is, whether this should include not only persons who follow the western system of medicine, but also those who have in different parts of the country practised any other system with repute and success, the president himself would desire to see included "members who honestly believe in his own system and practises it with a sincerity of purpose" (*sic*) The main part of the address, however, appears to be essentially (whatever topics may nominally be under discussion) an attack on the Government, and more especially on the Indian Medical Service, and its tenor may be illustrated by such phrases as the following

"Studied carelessness on the part of I M S officers in discharging the responsible duties cast upon them, namely, that of developing an Indian Medical Profession, the pre arranged method of keeping the Indian out of every opening where they could develop themselves, have been responsible for the present state of affairs", " those teachers who have developed only one form of speciality, namely, the speciality of possessing an overweening self-confidence, the speciality of rejecting all claims of the Indian practitioners to fair treatment, the speciality in belittling everything Indian", " this backdoor way of securing a few more lucrative posts for the members of the Indian Medical Service", (after referring to the heavy Indian mortality) " can nothing be done to prevent this enormous loss of man power in India? It is not necessary for me to mention that the history of the Government during the past 100 years has been such that we need not look for help or inspiration from the authorities'"

The resolutions passed at the conference are thirty-five in number, some deal with the Indian Medical Service, some with questions of registration, others take up questions of curriculum, or more general matters The fourth of the pamphlets, entitled "Some Problems of the Medical Profession in India", compiled by one of the joint honorary secretaries of the Association, brings together an address by Sir Nilratan Sircar to the conference of 1928, and correspondence and other documents relative to the four subjects of the co ordination of medical research in India, the reorganisation of the medical services, the Medical Council Bill, and the Bengal Council of Medical Registration We may briefly consider a few of the topics raised in the conference, while leaving others aside as of too limited general interest

The recognition of practitioners of the indigenous systems of medicine is advocated both by the president of the conference and by Sir Nilratan Sircar, who thinks that there should be chairs of Hindu medicine and of the Yunani system in the colleges, he would have us 'put ourselves *en rapport* with the genuine living representatives of the ancient medical art" in order to incorporate whatever of value there may be in the indigenous practice

It is perhaps natural at the present time, when national feeling is so strong among the educated classes, that Indians should express a belief in and seek to exploit these indigenous systems It is, of course, true that science is one, there can be no opposed eastern and western science, all students and practitioners belong to one body,—one body, that is, in so far as, and only in so far as, all recognise the same ideals and proceed on the same basic principle Annually at the Royal College of Physicians the Harveian orator of the year calls on his brethren, as he is bound by the terms of his office to do, to search out the secrets of Nature by way of experiment, and if a body of practitioners does this, or at least acquires a knowledge of, and accepts and bases its practice on, the results of the experimental method, won hardly and with difficulty through the ages, they are of the brothers of the true lineage and acceptable as such by the descendants of Hippocrates But to trust to ancient authority to the exclusion or neglect of more modern methods of research and their results, or to base the whole of practice, not on the body of scientific knowledge but on some single arbitrarily selected principle, such, for example, as that of homœopathy—this is to remain outside the brotherhood of science and the fellowship of those who carry on the torch of learning

The second principal feature of the speeches at the recent conference, the abuse of the Indian Medical Service and of Government, may be passed over briefly The conference was held in Lahore simultaneously with the National Congress, the beginning of so much native unrest, presumably the coincidence was designed, in order that the members of the conference might also attend the Congress, and that the conference might catch its fire and take its tone from the larger assembly Yet the conference can scarcely represent the attitude of more than a portion of the Indian medical practitioners—or at least one hopes not Certainly a very different picture is suggested by the contents of the *Transactions of the Seventh Congress of the Far Eastern Association of Tropical Medicine*, held in British India, and mainly at Calcutta, just over two years ago (see NATURE, June 22, 1929, and Mar 1, 1930) Though this congress was far from exclusively British Indian, the British and Indian members of the medical services and British and Indian practitioners naturally formed the bulk of the membership and contributed the majority of the papers, which contained a very large amount of work, much of it of a high order of merit, and if one may trust to the impressions gained by perusing the records of the meeting, one would say that the two races are working side by side in amity, with many personal friendships, and both producing much useful work

All that is of practical value in these publications seems to be contained in the pamphlet on "Some Problems of the Medical Profession in India" But here too the same spirit is apparent, thus one of the contributions states that "the Government, beyond reminding us that we are illiterate, has done practically nothing to educate us", which reads strangely to anyone who knows the enormous advances that have been made in recent years in education—elementary, secondary, and higher—by Government directly or with Government aid Again, "in measures for improving the health and social conditions of our people" Government "should not add their weight to the millstone that is already round the neck of our society", to those who know the magnitude of the Government's endeavours for such improvement, and how they are often in advance of general opinion in India, the suggestion contained in the last sentence is so false as to be merely grotesque

For the rest, there is much criticism of the

decision of Government to establish, in accordance with the findings of the Fletcher Commission, an Imperial Medical Research Institution at Dehra Dun, where the buildings of the recently displaced Forest Department would be available It is pointed out that Kasauli (where the present Central Research Institute is situated) is too isolated intellectually, though it has a good climate for research, being in the Simla Hills at a height of 6000 feet, Calcutta, or Bombay, on the other hand, though doubtless the climate is not so suitable or agreeable, have the advantage of being large centres of population, with universities, hospitals, and laboratories where research is going on in other branches of science, where team work would be possible, and clinical material available, but Dehra Dun has the advantages of neither, with the disadvantages of both It is quite possible that the contention is sound, it was announced in the House of Commons a short time ago that the question of the locality of the new Institute is to be reconsidered by the Government of India

The remaining questions—such as those of the relations of the military and civil branches of the I M S, the reservation of posts for the I M S, the All India Medical Council Bill, and the Bengal Council of Medical Registration—are too strictly medico political, and too complicated and thorny, to interest the majority of the readers of NATURE It may briefly be added that a new situation has recently arisen through the decision of the General Medical Council to withdraw its recognition of the medical degrees of Indian universities as qualifying for registration in Great Britain The controversy began in the limited opportunities (owing to Indian customs such as that of purdah) for obstetric instruction in India, and has lasted more than ten years, for some time past the recognition given to these degrees has been conditional, and been renewed for short periods, it now lapses entirely The matter can scarcely remain where it is, but it is not yet apparent what are to be the next steps taken in India

Botanical Exploration of Krakatao

The Problem of Krakatao as seen by a Botanist By C A Backer Pp iv + 209 (Weltevreden Visser and Co, The Hague Martinus Nijhoff, n d) n p

"VOLCANIC action", according to Sir Archibald Geike's "Textbook of Geology", "embraces all the phenomena connected with the expulsion of heated materials from the interior of the earth to the surface" The materials may, no doubt, have been pent up for some time in a simmering condition before the actual eruption, and in the case of a real volcano it is scarcely possible to predict when the eruption may occur

The book recently published by Mr C A Backer may be likened to what has been quoted above, but in this case the occurrence was timed to coincide with the opening of the Pan Pacific Science Congress held in Java last year Mr Backer has much to say that is of great interest and value in connexion with the Krakatao problem It is, however, unfortunate that he has written his account with so much acrimony, not unrelated, it would appear, to the fact that he was 'Formerly", as he states on the title page, "Government Botanist for the Flora of Java" His book deserves careful study, coming as it does from so critical a botanist, whose knowledge of the flora of Java exceeds that of any other worker in this field It is therefore much to be regretted that it is marred by the aspersions which he has cast on distinguished botanists, both dead and living, whose contributions to the Krakatao eruption history have come to be regarded as classics Why Mr Backer severed his connexion with the Buitenzorg Herbarium, where he was botanist for so many years, we do not know, but it is to be regretted that he has chosen the medium of a scientific work as a vent for the eruption in print of his own pent-up feelings

Mr Backer's book has been published forty six years after the eruption of 1883, and unfortunately none of the botanists and others who visited the Island in the earlier years are now living Though it will be agreed that much more might, and should, have been done in the way of detailed and prolonged investigation in the years immediately following the eruption, it is unnecessary to cast reflections on the investigations which Treub, Penzig, Raciborski, Boerlage, Clautriau, Valeton, Golenkin, Ernst, and others carried out at various times, since it is due to them alone that we possess such knowledge as we have of the state of affairs on the Island between the years 1886 and 1906

The main contentions with regard to the problem of Krakatao put forward by Mr Backer are that all vegetable life was not destroyed by the eruption of 1883, and that, except for the littoral flora, we know "nothing at all" about the manner in which the new vegetation has appeared Treub was the first botanist to visit the Island—in 1886, three years after the eruption. His visit was a brief one, and it is undoubtedly most unfortunate that an earlier

and detailed visit was not made, and that the mountain itself was not then, or during any subsequent visits, fully explored by a botanist There is good reason to assume that the ash covering on the steep south-east mountain slopes was not very thick On the lower slopes and on the shore, however, the ash covering was deep, and no doubt it was of so high a temperature that all the plants on and near the shore were destroyed Tropical rains must certainly soon have removed the lighter ash deposits on the higher mountain slopes, and if, as Mr Backer brings good evidence to show, the fine ashes which fell back on the summit were quite cooled down in falling from a great height, it is conceivable that plants with rhizomes and underground parts were able to recover and afterwards to refurnish the higher parts of the Island, while seeds and fruits may also have survived Treub, of course, stated, from his examination of the lower parts of the north west side of the Island near Zwarte Hock, that every living thing had been destroyed, yet in 1888 he records that he could distinguish plants growing near the top of the cone (some 800 metres in height), from the vessel on which he was sailing

It certainly is an unsolved problem, if Treub's observation was correct, how such plants could have originated, since transport of seed by wind from Java across so wide a stretch of sea seems scarcely possible Mr Backer himself had the opportunity of visiting Krakatao in April 1906, with Ernst, Pulle, and D H Campbell, but as he had not properly equipped himself for the expedition, he failed to climb higher than some 400 metres up the mountain Had he reached the upper slopes, the botanical information he could have given would have been of the utmost value As, however, he did not himself fully explore the mountain or make the detailed investigation which, as he rightly points out, was so much needed, his criticisms of others, and more especially of Dr Docters van Leeuwen, the present director of the Buitenzorg Gardens, seem singularly out of place

It is easy in these days, so long after the eruption, to point out the shortcomings of those who paid the early visits to the Island, but it must be remembered that the climbing of the deeply and intricately fissured mountain side, covered with ash and pumice, was fraught with difficulties well-nigh defying the attempt The ravines had almost vertical sides, and the ascent of the slope entailed a series of constant descents and ascents in and out of the deep fissures and ravines which cut the mountain side in all directions

Treub, it will be remembered, found eleven ferns growing on the rocks at Zwarte Hock in 1886 These are all species which grow on steep cliff walls, and it is conceivable, owing to the nature of their habitat, that they may have survived the eruption either by means of rhizomes or spores lodged in clefts of these basaltic cliffs, since neither pumice nor ashes could have lain there to any depth, and would quickly have been washed away by the rain In fact, two months after the eruption, Verbeek found the old rocks of Zwarte Hock locally bare, so that in well-sheltered localities part of the old fern vegetation may have survived as Mr Backer suggests

Mr Backer has a good deal to say about the incorrect determinations of the plants collected on the various visits As a systematist he is doubtless correct, but one cannot help objecting to the manner in which he expresses his criticisms With regard to the re covering of the Island, it is evident that the littoral vegetation is entirely new, and is due to seeds and fruits which have been washed up on the shores Mr Backer brings forward many arguments to show that very few, if any, seeds could have been wind-borne as has been assumed, though he considers seeds may have been brought over by birds and almost certainly by the many visitors and fishermen who have visited the Island His main contention, however, is that the old vegetation was not entirely destroyed, as stated by Treub, but that on the steep cliffs of Zwarte Hock, and on the south and south east higher slopes, living plants persisted From these remnants of the old vegetation he believes the slopes may have been reclothed downwards, and the fern population of the cliffs restored The new vegetation was certainly not long in making its appearance, since a year after the eruption an observer, on a ship, thought he saw some plants growing near the summit of the mountain

The mode of origin of the new vegetation of Krakatao, except for the littoral plants, must therefore be regarded as unsolved, since we know so little of what was actually growing on the Island in the first few years after the eruption, and it was not until twenty-three years had elapsed that any attention was paid to the vegetation on the eastern and south-eastern sides

Mr Backer's conclusions at the end of his book are typical of the spirit in which it is written He writes

"I have tried to find the very few bones in these wagon-loads of rubbish and will finish by stating once more, that

1 It is not at all proven that by the eruption of 1883 all vegetable life on Krakatao was destroyed

2 Even if this could be proven, we know—with the exception of the littoral flora—nothing at all about the manner in which the new vegetation has appeared Only guesses without scientific value have been made, but no reliable observations nor experiments

3 Therefore the Krakatao problem can neither now nor in the future either be posed [? proved] or solved, and is of no importance at all for Botanical Science "

Ovarian Secretions

The Internal Secretions of the Ovary By Dr A S Parkes (Monographs on Physiology) Pp xv + 242 (London, New York and Toronto Longmans, Green and Co, Ltd, 1929) 21s net

DR PARKES is one of the best known authorities on this branch of physiology concerned with internal secretions, and his book gives a comprehensive survey of all the past and current work carried out on the subject by the leading men of science of all countries During the last ten years or so a much keener interest has been taken in the properties of the ovarian secretions, as it has been gradually realised what an important part they play, and thus the amount of experimental data has been rapidly accumulating This has greatly added to the difficulty of Dr Parkes's task, as he has had to exercise great discretion in the choice of his subject matter, and it is never easy to distinguish between the important and relatively unimportant work of contemporaries, and to realise which views will stand the test of time and which will in later years prove to be erroneous It can, however, be seen at once that no space has been wasted in dealing with vague hypothetical considerations and views which are not supported by solid evidence, but only those are included which have been proved experimentally The book is very well and fully illustrated throughout, thereby greatly adding to the value and clarity of the text It is easy to see that the experiments on animals to show the functions and properties of the ovarian secretions are the careful work of experts, as they are all of them conclusive and have been carried out with the greatest accuracy

The book is divided into sections, the less detailed ones dealing with such subjects as the morphology of the female reproductive organs coming first There is no need for more than a very general account of this, as numerous anatomical and histological text-books contain fuller descriptions The author then passes on to a review of sexual periodicity in the female mammal, showing how certain animals have salient points in common There is a very interesting account of types of œstrus cycle in those animals in which it has been sufficiently studied, and this is followed by a section on the ovary as an organ of internal secretion

The œstrus producing hormone is dealt with by Dr Parkes in detail, no full account of this has previously appeared in the literature up to date, and the description of its preparation, properties, and administration is excellently done and will be found of great interest by all readers In the section dealing with the ovary and the anterior pituitary body, the author shows that it is only of recent years that the importance of the relation between these two has been discovered, and he discusses the many problems connected with this relationship

A detailed account of the chemistry of œstrin is given, stating the various methods of preparation with references so that those interested can obtain a full description From the general point of view, the most important section is the one dealing with the physiological effects resulting from its administration to animals The source of the material is also discussed and the significance of its occurrence in the bodily secretions of animals and men

In conclusion, we feel that this work will become a classic, and trust that new editions will appear at frequent intervals

Robert Hooke

Early Science in Oxford By Dr R T Gunther Vol 6 *The Life and Work of Robert Hooke* (Part 1) Pp xxiv + 396 31s 6d Vol 7 *The Life and Work of Robert Hooke* (Part 2) Pp viii + 397 806 31s 6d (Oxford The Author, Magdalen College, 1930)

THE two latest volumes of Dr Gunther's series of books on early science in Oxford deal with the life and work of Robert Hooke Dr Gunther makes high claims for the hero of his story, and if we cannot accept quite all his claims, we can at least agree that Hooke was one of the most prominent of those remarkable Englishmen who made the second half of the seventeenth century illustrious in the history of science

The volumes before us contain as preliminary

matter an essay by Dr Gunther in the form of a preface, and a reprint of Richard Waller's "Life of Hooke", first printed in 1705, with added extracts from John Ward's 'Lives of the Gresham Professors" (1740), and Aubrey's "Short Lives" The bulk of the work consists of notes on Hooke's experiments, discoveries, and inventions, extracted from the records of the Royal Society and other sources

Hooke was born in 1635 at Freshwater, in the Isle of Wight Though a weakly child, he was "very sprightly and active", amusing himself by "making little mechanical Toys" From Westminster School he went as a chorister or servitor to Christ Church, Oxford Here his early mathematical and mechanical aptitudes brought him into touch with Oxford men of science, and he became chemical assistant first to Thomas Willis, and then to Robert Boyle, whose "Pneumatick Engine", that is, air pump, owed much to Hooke's skill In 1656 or 1657, Hooke invented the anchor escapement for pendulum clocks, and, seeing the practical importance of accurate chronometry for the determination of longitude at sea, was led "to the use of Springs instead of Gravity for the making a Body vibrate in any Posture", and thus to the spring controlled balance wheel of watches and chronometers His attempt to obtain a grant of a satisfactory patent for this having failed, he put aside the application of the invention to chronometers, which first became practicable when in 1761 John Harrison corrected the balance wheel for thermal expansion

In 1662, Hooke was appointed curator of experiments to the newly founded Royal Society, and left Oxford for London, residing at Gresham College in Bishopsgate for the rest of his life As Miss A M Clerke says in her admirable account of Hooke in the "Dictionary of National Biography"

"The Registers of the Royal Society testify to the eagerness with which Hooke hurried from one inquiry to another with brilliant but inconclusive results"

Dr Gunther acknowledges this characteristic in other terms

"On the other hand, the fact that he had noted an idea in one of his synoptic tables probably led to his claiming it as his exclusive copyright This may explain why it not infrequently happened that when some new discovery was mentioned to him, he was apt to think that he had himself made it long before, whereas he had merely considered the possibility of such a discovery, and had noted it in an appropriate place in an 'algebra' With the onrush of other and newer interests, he had not been allowed time for following out the investigation suggested"

Nevertheless, Hooke's work comprises a long list of solid achievements Perhaps he is best known by Hooke's Law of Elasticity, *Ut tensio sic vis*, but that is merely one among many other discoveries and inventions Besides his mechanical ingenuity, shown in his improvements in watches and clocks mentioned above, and in the invention or improvement of numerous other scientific and technical instruments, he was a busy and successful architect, building Montague House, the Bethlehem Hospital, and the College of Physicians, and acting as surveyor to the City of London Moreover, he made notable advances in biology and chemistry he was one of the earliest microscopists, and described the cellular nature of living tissue, he proved that life could be maintained by blowing air over the surface of the lungs without muscular movement, and partly anticipated Mayow in a true explanation of combustion

Dr Gunther claims that 'it is certainly hardly fair to Hooke's memory that the coloured diffraction bands discovered by him should be everywhere known as Newton's rings" But the mere observation of the colours of thin plates—even the blowing of glass thin enough to show them—seems less meritorious than Newton's detailed study, with careful measurements and a calculation of the intervals of 'fits of easy transmission"—the first determination of the wave length of light Hooke's credit is that of the pioneer, who makes discoveries and suggestions and passes on The demonstration of the colours of thin plates, the idea that light was a wave motion, and a wave motion transverse to the direction of propagation, the attempt to measure the parallax of a fixed star, the proposals for flying machines, all are examples of Hooke's insight into possibilities for the achievement of which the time was not ripe

Probably Hooke's greatest work for science was done as 'curator' and later as secretary of the infant Royal Society He demonstrated not only his own experiments but also those of others whom he often helped in their difficulties If he sometimes showed a querulous temper, he had valid excuses, as Dr Gunther points out But, in the main, he set the fashion of that quiet and self-effacing helpfulness for which so many officers of the Society have been remarkable from Hooke's day to this How much Hooke did to further science at a critical stage in its history is well seen in Dr Gunther's two useful volumes

Our Bookshelf

Fungi and Fungous Diseases (Adolph Gehrmann Lectures of the University of Illinois College of Medicine, 1926) By Prof Aldo Castellani Pp iv + 203 + 4 plates (Chicago, Ill American Medical Association, 1928)

SIR ALDO CASTELLANI'S latest contribution to medical mycology is based on a course of lectures delivered by him in 1926 as Adolph Gehrmann Lecturer of the University of Illinois College of Medicine It is well recognised that the advent of the bacteriological era retarded considerably the development of mycology in its relationship to disease of man and animals, and even now, in spite of our vastly increased knowledge of pathological conditions associated with fungi, the systematic classification and nomenclature of these fungi have been the concern of but few professional mycologists Castellani has worked largely in this field and he has been able to combine with considerable success his well known clinical interest and experience of tropical skin diseases of fungous origin with studies of the fungi concerned

The inexpert reader will, we are afraid, be rather repelled than otherwise by the elaborate classification tables and well meant simplifications of them presented by the author He will note recent tendencies to replace old familiar genera by new and unfamiliar ones He will be grateful, however, for the author's account of the fermentative activities of fungi and the use to which these activities may be put not only as an aid to their systematic classification but even to the detection of particular carbohydrates in pathological fluids The author has given much attention to this subject, and, in particular, his employment of differential fermentation effects by known fungi in order to detect the presence of the rarer carbohydrates in fluids has aroused wide interest

The second half of the book deals with pathological conditions in man that are due to fungi and includes a description of interesting tropical skin diseases, to some of which Castellani was the first to direct the attention of dermatologists It contains some excellent photographs and coloured plates of skin lesions It is clear that a wide field is open for the co ordinated research of clinical pathologist and professional mycologist J C G L

Standard Methods for Testing Tar and its Products Pp xxix + 295 + 10 graphs (London Standardization of Tar Products Tests Committee, 1929) 7*s* 6*d* net

To ensure uniformity of analytical results on such composite products as many of those which fall within the generic term of ' tar products ', standard processes are, in most instances, essential The present volume is the outcome of a vast amount of work, carried out by a committee formed as the result of the advocacy in 1926 of the need for such standardisation In addition to members of the trade, the committee included—or rather includes, for it is still in being—external bodies who represent in some measure chemists approaching such work for the first time Further, the co operation of the National Physical Laboratory was sought to consider the question of glassware and, as a result, an extensive schedule of apparatus is appended

Introductory sections deal with the problem of adequate sampling, so essential if the subsequent tests are to be of any value and with the general principles of distillation and of the determination of specific gravity Then follow the methods laid down, under the general headings (1) crude tar, (2) refined tar, including road tar, (3) lower boiling fractions, (4) tar acids, (5) naphthalene, (6) tar bases, (7) creosote oil, (8) crude anthracene and (9) pitch , many of these sections are further subdivided Appendices include, in addition to that on glassware, tables of constants and equivalents and a convenient collection of graphs, some of an elaborate character For general laboratory use, the set of graphs may be obtained separately

No claim to finality is made , indeed, provision is made for the subsequent inclusion of such additional tests as the committee may deem desirable Only those who have been in any way associated with the project can fully appreciate the enormous amount of labour, well repaid, in the production of this book, which may be recommended with confidence to all who have to deal with ' tar products ', much or little Commendation, indeed, is insufficient to such, the volume is a necessity

The Romance of the Portuguese in Abyssinia an Account of the Adventurous Journeys of the Portuguese to the Empire of Prester John , their Assistance to Ethiopia in its struggle against Islam and their Subsequent Efforts to impose their own Influence and Religion, 1490-1633 By Charles F Rey Pp 319 + 16 plates (London H F and G Witherby, 1929) 18*s* net

IN the volume under notice, Mr Rey tells the story of the endeavours made by the Portuguese nation for a century and a half to secure a footing in Abyssinia This was an outcome of the policy of exploration and expansion initiated by Henry the Navigator When Pedro da Covilham and Alphonso da Payva were sent out in 1487 in search of Prester John, it was not entirely in a spirit of romantic adventure They were also instructed to search out the sources of the wealth of the East and of its commercial products They stumbled, by accident as it were, on Abyssinia , but in the dispatches which they were allowed to send home, though they themselves were never permitted to leave the country, they reported that they had found the legendary kingdom of their search

Mr Rey here tells the story of the subsequent growth of Portuguese influence at the court of the Negus, strengthened as it was by the help which they were able to give the Abyssinians in their resistance to Islam, and of the collapse of both military and missionary adventure which ended in the final expulsion of 1633 Mr Rey's story is well told, with a full appreciation of the bearing of Portuguese policy and its after effects on the fortunes of Abyssinia The book is illustrated by some well-chosen reproductions of old prints.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Test of a Relativity Postulate

CLERK MAXWELL'S original suggestion, revived in NATURE for April 12, p. 566, was in danger of being lost sight of, although it has been renewed independently from time to time; see, for example, *Phil. Trans.*, 1893, p. 784. The prevailing relativity postulate that motion through the ether is undetectable, or in another form that no motion of an observer can affect his determination of the velocity of light in free space, has not yet been actually and directly verified. Common sense seems to assert that motion of source can have no influence on waves after they have left it, while motion of receiver should subjectively affect their speed of arrival; but this would be contrary to the relativity postulate.

Attempts to observe a relative ether drift, by experiments made on a to and fro journey between terrestrial stations, appear neutralised by a FitzGerald contraction: a first order test is needed; and that can only be furnished by astronomy. The Jovian system is a clock to or from which we are sometimes approaching, sometimes receding; and the consequent essentially Doppler effect (change in satellite periods) is well known. But a Doppler effect, though not caused by a drift, can be modified thereby if the drift is inconstant. Syrens and church bells presumably wail during gusts. The orbital motion of the earth is equivalent to a variation in the drift of the solar system; so there may be an observable modification for the eclipse intervals of Jupiter's satellites. Quadruple satellite motion may be too complicated for the test; that is a question for astronomers: but there is a previous question, the one apparently first propounded by Maxwell; and I do not see that the answer is as yet assuredly in the negative.

If, however, waves are more like projectiles than used to be thought, several lines of reasoning will have to be modified (see, for example, *Proc. Roy. Inst.* for April 1, 1892, or NATURE, vol. 46, p. 497), and the relativity postulate may turn out to be justified by a curious interlocking with the quantum.

OLIVER LODGE.

Normanton House,
Lake, Salisbury,
April 14.

Mechanism in Nerve Centres

IN NATURE of Dec. 14, 1929, there appears a letter from Prof. Alexander Forbes attacking the arguments I have made in criticism of the mechanistic interpretation of reflex functions.[1] I believe this challenge ought to be taken up, because it is both courteous and impersonal in tone and because I fear that the well merited dignity of my critic's name may lend undue weight to his arguments among those who are unfamiliar with neurology.

Prof. Forbes's criticisms are focused on a statement of mine that mechanism cannot account in full for the function of nerve centres because a machine "cannot change itself or its functions to meet new conditions; it does not improve its performance with practice; it cannot perform some particular function depending originally on one part, after that part has been destroyed." Had he proceeded with this quotation he would have added: "An internal combustion engine cannot learn by itself to run as well at a high altitude as at a low. If a motor car turns in at a certain gate 999,999 times, it will have no more tendency to leave the road at that point the millionth time than it had the first. If one cylinder of a motor is put out of action, the speed and power of the engine is reduced in a mathematically predictable proportion; or the loss of a small part in a complicated mechanism may mean the total cessation of function, as in a watch that loses a wheel. Yet these are kinds of things which the central nervous system may do—or do without."

These explanatory examples Prof. Forbes omits: he denies the generalisation and cites other examples from the mechanical world to support his claim. These show, I believe, that he does not understand the difference between living and mechanical processes which constitute the problem under discussion, for he uses changes in the mode of operation in a machine as instances of adaptation. Biologically, adaptation involves the development of a response or of a structure, which has not previously existed in the organism. Prof. Forbes's examples are of changes in mode of functioning of machines that have been designed so to change.

Prof. Forbes first cites the case of a mechanical beetle that turns away from the edge of a table and walks in another direction. His second is the stabiliser of an aeroplane which operates the controls so as to reinstate it on its course when deflected by a 'bump'. A biologist would not regard these as adaptations to new situations because no reaction previously foreign to these 'organisms' has appeared. Perfection of function with practice he illustrates by a motor that runs better after the first 500 miles of use. But this is mere elimination of friction in the bearings, etc., which is, theoretically, part of the process of manufacture and may indeed be accomplished without running the engine at all. 'Running in' does not produce any increase in power generated as would happen were there true perfecting with practice. A true analogy does exist between the regulation of the order of firing in the cylinders of an internal combustion engine and the co-ordination of muscular contractions in the animal body. Both depend on accurate timing, and the better the timing the more power is there produced in both cases. Would an eternity of practice make an engine improve the timing of its explosions?

As to vicarious function in the central nervous system, which means the reappearance of a function that has been originally mediated by some part which is destroyed, Prof. Forbes thinks that "an ingenious mechanic might devise a number of ways in which a machine could be made to change automatically from one mode of operation to another *in consequence* of the failure of some of its parts; for example, a steam pipe might be provided with an automatic valve which, if the pipe burst, would divert the steam through another pipe. Electrical devices which perform essentially this function are actually in use in electric railways." But these are not examples of vicarious functions. The use of the word 'automatic' proves that the mechanisms cited were designed to use alternative parts. After destruction of a 'centre' in the central nervous system, the function previously operating through this part does not automatically reappear in the working of another part. The recovery is slow and laborious: moreover, the parts which take over the function could not have been designed as specific alternative mechanisms. Instances of vicarious function in the brain are notorious, but I will cite one which is more in Prof. Forbes's

field, namely, the spinal cord Lashley[2] has recently shown by double hemisection of the spinal cord that control of the limbs is regained in three months after the permanent interruption of all the long spinal paths from the brain to the motor centres for the limbs It takes three months for the nerve impulses to 'learn' to follow a circuitous route they must travel through path ways the original function of which it was to connect up adjacent centres in the cord If these short fibres were designed as an alternative route for impulses from the brain, they would come into service as soon as the immediate effects of the operation had passed away In man the improvement of function after injury to the spinal cord may go on for years

If one assumes, as do mechanists, that the principles of mechanical and biological functions are identical, the problem of discriminating between them does not arise, and errors, such as those cited above, are quite understandable But Prof Forbes's enthusiasm carries him to more uncritical lengths He devotes his longest paragraph to knocking down a straw man He alleges that I claimed the production of impulses in the central nervous system to be a performance of which no machine could be capable He then argues that machines could do such things With this argument I am in agreement, for it destroys a claim I have never made or contemplated

The reader may, perhaps, think that these are mere debating points and that differences between mechanists and non mechanists are philosophical squabbles without practical significance The very contrary is true, as I think anyone will agree who has studied the way the minds of investigators work Roughly speaking, we find only that for which we seek the hypothesis precedes the discovery The mechanist—in so far as he is faithful to his creed—finds only the mechanical factors underlying the functions he studies and has no further curiosity as to the nature of the functions themselves But for the Pasteurs and Darwins of science, functions, *qua* functions, have had a fascination

New Data on Cellulose Space Lattice

IN previous investigations made to determine the space lattice of cellulose, the material used was in the form of minute fibres Due to the cylindrical form of the fibres, it was not possible to determine directly by experiment the relations that exist between the planes which are parallel to the long axis of the fibre Several attempts were made to construct a lattice which would fit the diffraction data, but no common agreement was attained[1] The principal difficulty was in the interpretation of the reflections which appeared on the 'equator' in spot diagrams when the X ray beam was perpendicular to the long axis of the fibres, and which appeared in the line diffraction patterns whenever the beam was parallel to the long axis In both cases the planes were evidently parallel to the long axis, but no experimental evidence was available to show how they were situated with respect to one another

New data which clearly bring out that relation were obtained from a plant in which the cellulose is deposited in relatively large sheets instead of in minute cylinders The plant is *Valonia ventricosa* It is a green alga which grows in the form of a single celled hollow sphere often 20 mm in diameter The wall of the sphere is thickened by depositions of cellulose from the inside in thin sheets making the wall many layers in thickness

Line diffraction patterns were made from a layered block composed of many pieces of the wall of this plant The interplanar spacings computed from the lines correspond to those from fibres, indicating an identity of molecular structure in the two forms—sheet and cylinder When pin-hole photographs were made the location of the planes in question was made clear In Fig 1 from fibres and Fig 2 from *Valonia* sheets, the reflections in which we are interested are indicated by the spots lettered A_1, A_2, and A_3 They appear in a row along the 'equator' in the pattern from the fibres, where A_1 and A_2 are partially superposed making a wide spot But in the pattern from *Valonia*, A_1 is 90° from A_2 The former was produced by planes which were parallel to the surface of the sheets, while A_2 was produced by planes at right angles to the surface, that is, the planes reflecting to A_1 and A_2 respectively were at right angles to each other A_3 appeared as four maxima lying between A_1 and A_2 Here for the first time the relation between these three sets of planes seems to be clearly demonstrated In both spacing and angular position the diffraction maxima are in agreement with an elementary cell in which the planes (010) are parallel to the surface of the cell wall and are represented by planes spaced 6 10 A, the planes (100) are perpendicular to the surface of the cell wall and are represented by 5 33 A spacings, and the diagonals (110) are represented by the maxima, A_3, spaced 3 93 A These three interplanar values are probably better values for cellulose than those so far published, because the lines produced by *Valonia* are sharper and more clean cut than those obtained from fibres

FIG 1 —Pin hole diffraction pattern from fibres

FIG 2 —Pin hole diffraction pattern from *Valonia*

The significance of the new data lies in this, that while the c axis only can be determined directly from fibres, the data from *Valonia* make it seem fairly certain that now the *a* and *b* axes also may be experimentally determined and that they are represented by A_2 and A_1 respectively of Fig 2 Based on this new evidence the elementary cell for cellulose is practically as reported by Sponsler and Dore for fibres With the slight refinement of measurements, made possible by *Valonia* diffraction lines, the axial dimensions for cellulose are

$$a = 10\ 7\ \text{A}\ ,\ b = 12\ 2\ \text{A}\ ,\ c = 10\ 3\ \text{A}$$

The angles between them are within 2° or 3° of right angles

Complete details of the work with *Valonia* will be submitted elsewhere

O L Sponsler
University of California at Los Angeles

Prof Sponsler is to be congratulated on his discovery of a plant in which the cellulose crystals are arranged so favourably for X ray analysis The results help to place the determination of cellulose structure on firm ground Prof Sponsler does not refer in his list of papers to certain attempts that have been made to produce artificially the same sort of special arrangements as he has now found in *Valonia* For example, Mark and Susich, having prepared a sheet from tunicin and having stretched it in one direction, were able to obtain an X ray diagram of the same character as that of Prof Sponsler's Fig 2 (*Zeit f phys Chem*, 4, p 433, Fig 3D, 1929) They, as Prof Sponsler does, deduced that the planes with spacings 6 08 and 5 45 (Sponsler 6 10 and 5 33) were nearly at right angles to one another, while the plane with spacing 3 95 (Sponsler 3 93) was inclined at about 45° to each of the others

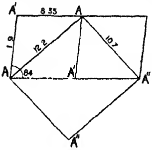

Fig 1

Prof Sponsler describes the cell as nearly orthorhombic with axes 10 7, 10 3, 12 2 The description of Mark and his collaborators is

$$a = 8\ 35,\ b = 10\ 3,\ c = 7\ 9,\ \beta = 84^\circ$$

The two descriptions, though they differ apparently, are almost equivalent The identity period along the fibre is the same in both, namely, 10 3

Prof Sponsler's cross section is $A\ A\ A''\ A''$ in Fig 1, that of Mark and others is $A\ A'\ A\ A'$ In the former case, A and A'' represent molecules or molecular chains in similar positions, with A' differing somewhat In the latter case, all the A's are identical The larger cell contains twice as many molecules as the smaller

Pressure Effects in the Band Spectrum of Calcium Hydride

Some years ago Mulliken (*Phys Rev*, 25, 509, 1925) reported a band in calcium hydride (CaH) at λ3533, having a very unusual structure The band was photographed at low pressure (~40 mm hydrogen) and is composed of single P and R branches, which are abruptly cut off at P (11½) and R (9½) As no more bands appeared corresponding to any higher vibrational states in the molecule, the effect was interpreted as a manifestation of some very unstable conditions in the initial C state Indeed, it was later supposed that the molecule dissociates by pure rotation, and Franck and Sponer (*Gött Nachrichten*, 241, 1928) calculated the dissociation energy of the C level to be about 0 09 volts

In connexion with some work on the pressure effects in band spectra at present going on in this laboratory, we undertook an investigation on this rather interesting band, varying the hydrogen pressure in the arc from 10 mm of mercury up to seven atmospheres We found that the entire spectrum of calcium hydride was brilliantly increased with the pressure In the C band a very remarkable effect appeared At high pressure, the P and R branches were strongly developed to about $J \sim 40$, the first few lines above the critical value $J = 10\frac{1}{2}$ being somewhat diffuse In addition, a number of new bands appeared, apparently forming a band system, the vibrational quantum numbers (v' v'') of which are here given

Heads of Bands in λ (Air)

v'' \ v'	½	1½	2½	3½	4½	5½
½	3533 6	3367 6				
1½	3696 6	3515 4	3356 3			
2½			3498 1	3346 5		
3½				3482 0	3337 6	
4½						3330 8

The correctness of this scheme has been checked by a comparison with other band systems in calcium hydride having a common final state $^2\Sigma$ There are numerous interesting details in the pressure effects on the C bands, for example, the appearance of some diffuse doublet components of the P and R series, apparently forming the missing components to be expected in a $^2\Sigma - {}^2\Sigma$ transition A complete description, including the analyses of new band systems in the visible and the near infra red, will, however, be published later

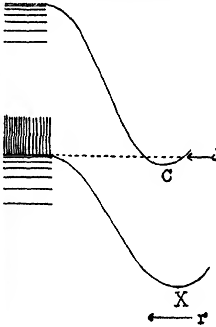

Fig 1

From the observations mentioned above, the following conclusions may now be drawn The abrupt cut off in the C band at low pressure is not due to an extremely small D value of the C level, but must be caused by perturbing influences from some unknown electronic level X, as shown in Fig 1 The effect is considered as a predissociation of the C-state into the

continuous region above this X level. One is tempted to say that the unusual band of Mulliken appears in the spectrum only due to the dipping of the C level into the region of discrete *Eigenwerte* in X. According to the theory of Kronig (*Zeit. f. Phys.*, **50**, 347; 1928) the Λ of the perturbing X differs from that of the C level by zero or ± 1. The C level is interpreted as a $^2\Sigma$ state ($\Lambda = 0$), so the X level must be either a $^2\Sigma$ or a $^2\Pi$ state ($\Lambda = 1$). The nature of the effect—the appearance of a great number of additional lines at high pressure—leads us to adopt the first of these alternatives as the correct theory.

Pressure effects of similar character, although due to interactions between Π and Σ states, have recently been reported by E. Bengtsson and R. Rydberg (*Zeit. f. Phys.*, **59**, 540; 1930) in the spectrum of aluminium hydride. Mr. G. Stenvinkel has interpreted this effect in terms of Kronig's theory. His hypothesis is readily applied to the effects in calcium hydride, so that we may refer to his paper (*Zeit. f. Phys.*, in press) for further details in the mechanism of the pressure effects.

The Absorption Spectrum of Vitamin D

In 1929 we published evidence (*Proc. Roy. Soc.*, B, **104**, 561; 1929) showing that in preparations made from ergosterol by exposure to ultra-violet radiation, and subsequent removal of unchanged ergosterol, there was a close correlation between antirachitic activity and intensity of absorption for radiation of wave-length 280 mμ. On this and on other evidence we argued that it was probable that vitamin D was the substance present in these products which was responsible for the intense absorption band with heads at 280 mμ and 271 mμ (substance A). We have now obtained definite evidence that this inference is not correct, and that the reactions which occur on irradiation of ergosterol are more complex than then appeared probable.

We have succeeded by the use of light filters and other methods in obtaining preparations showing very high antirachitic power but relatively low absorption at 280 mμ. Further, by irradiating ergosterol with radiation only of wave-lengths longer than 280 mμ (through a filter of xylene), removing the unchanged ergosterol and re-radiating with short wave-lengths only (through filters of chlorine and bromine), we have often obtained during our second radiations a considerable rise in absorption at 280 mμ simultaneously with a destruction of antirachitic activity. In this way we have obtained mixtures showing high absorption closely resembling that which we defined as due to substance A (and almost certainly due to this substance) but showing only low antirachitic activity.

Thus, while it is not yet possible to say what is the true absorption of vitamin D, it is evident that the substance showing the very intense maximum at 280 mμ produced in the early stages of the irradiation of ergosterol by a mercury vapour lamp (without light filters) is not vitamin D.

This non-identity of the two substances is in agreement with the findings of Reerink and Van Wijk (*Biochem. Jour.*, **23**, 1294; 1929) and Windaus (*Nachr. ges. Wiss. Göttingen*, 36-57; 1930).

Presence of a Yeast in the Death Watch Beetle (*Xestobium rufo-villosum* De G.).

My attention has been directed to the paper by Campbell in the *Biochemical Journal*, vol. 23, No. 6, 1929, in which reference is made to the work of Uvarov (1928), who suggests that wood-eating insects may partially digest wood particles with the aid of the secretions or excretions of micro-organisms, or even digest the micro-organisms themselves. Campbell, as the result of his work, suggests that it is probable that intestinal micro-organisms play a prominent part in the biology of the larva. In view of these suggestions, it is thought to be of interest to direct attention to the fact that, whilst conducting an investigation under the direction of the late Prof. H. Maxwell Lefroy during 1924, I found that a yeast was invariably present in larvæ and adults of the death watch beetle. While no evidence was obtained that the yeast was actually concerned in the digestion of wood particles, a number of facts concerning the distribution of the yeast in the various stages of the insect was determined. Dr. S. G. Paine, of the Imperial College of Science, was also closely concerned with the investigation and made a number of attempts to cultivate the yeast.

Briefly, the facts ascertained with regard to the yeast were as follows:

1. Yeasts were found in large numbers in the hepatic diverticula and closely connected portions of the alimentary canal of the adult male and female insects, and also in the larvæ. They are enclosed within the cells of the hepatic diverticula of young larvæ, but free in the diverticula of older larvæ and of the adult insects.
2. Yeasts are extremely rare in portions of the alimentary canal other than those mentioned above.
3. Yeasts are to be found in large numbers in the spermathecæ and vagina of the adult female, from whence they are doubtless conveyed to the eggs.

Unfortunately, when I left the Imperial College to take up my present appointment, the work had to be discontinued. An important fact, which still requires elucidation, is the means whereby the yeasts migrate from the hepatic diverticula, in the larva, to the spermathecæ of the adult female. It would seem that this can only take place in the pupal stage, during histolysis. The yeasts also require tracing from the egg to the newly hatched larva.

It is hoped that the observations here recorded may be of assistance to those endeavouring to elucidate the metabolism of the death watch beetle.

Integration of Sunlight

In their letter on this subject in Nature of Mar. 22, p. 447, Messrs. Teegan and Rendall refer to a photo-electrolytic method. The electrolytic method of integration does not appear to be very sensitive.

For investigation of the flow of heat at a window, into or out of a room, apparatus has been devised which produces an electromotive force of 70 micro-volts for a heat flow of one British thermal unit per square foot per hour and affords a continuous record of the flow. This has been described in the *Philosophical Magazine* (**8**, 841, December 1929).

With intermittent sunshine the continuous record is naturally difficult to integrate and an integrator has therefore been devised to 'meter' the heat flow

This instrument works from A C mains and operates a six-figure counting train, one unit corresponding to one microvolt hour The integrator is arranged to handle electromotive forces ranging from −150 to +300 microvolts A description of the apparatus is being prepared for publication

Method of Registering Multiple Simultaneous Impulses of Several Geiger's Counters

PROF W BOTHE in the *Zeitschrift fur Physik* (vol 59, p 1) describes a method for registering simultaneous impulses of two Geiger's counters, which depends principally on the working of a two grid thermionic valve Lately, I have had the opportunity of experimenting with a circuit which perhaps is simpler and at the same time has the advantage that it can be extended also to the registering of triple simultaneous impulses or even more The circuit adopted (for triple coinciding impulses) is shown in the accompanying diagram (Fig 1)

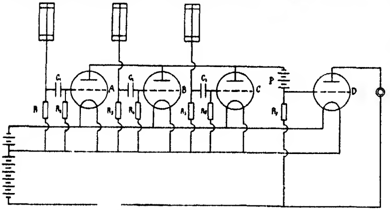

FIG 1

$$R_1, R_3, R_5 = 5\times 10^9 \text{ ohms}$$
$$R_2, R_4, R_6, R_7 = 8\times 10^6 \text{ ohms}$$
$$C_1, C_2, C_3 = 10^{-4}\ \mu F$$

The positive electrodes of the three counters (in my experiments I have used Geiger's wire counters) are electrostatically coupled to the grids of the three valves A, B, C In normal conditions these grids have a zero potential, whenever a discharge occurs they become negative, thus interrupting the current flow

As the resistance R_7 is very great compared with the internal resistances of the valves A, B, C, their anodes are at a potential near to zero The grid of the valve D (for the introduction of the auxiliary battery P) is at a slight negative potential This potential varies very little when only one or two counter tubes are working, while it undergoes a sudden rise when, for the simultaneous working of the three counter tubes, the current is interrupted in all the three valves

The consequent variation of the anode current (eventually amplified by a fifth valve) is acoustically detected by a telephone

The circuit arrangement, in regard to the counter tubes, is perfectly symmetrical, a condition which is not fulfilled in the circuit of Prof Bothe, because the grids of the two-grid valve have rather different characteristics

It appears that the triple coincidences method is the only one available for studying the form of the paths of cosmic rays, and I mean to employ it in experiments on the magnetic deviation of these radiations

The Conversion of α Benzilmonoxime into the β Oxime by Animal Charcoal

DURING the course of an investigation into the properties of the isomeric monoximes of benzil, we have made the following somewhat startling observation

We have been able to devise a method for estimating mixtures of the α and β oximes and have shown that the α oxime shows no appreciable change into its isomer (which is the more stable of the two) in solution in alcohol or benzene at 50° in a period of thirty six hours, and that the change is not accelerated by acids or alkalis when present in small concentration On the other hand, if a benzene solution of the α oxime is boiled with animal charcoal for a few seconds, the change is complete and no α oxime can be detected in the solution

Finely powdered soft wood charcoal and powdered silica gel showed no such effect, the α oxime being recovered unchanged Finely divided calcium phosphate is also without action That the conversion does not arise from the action of catalysts dissolved from the charcoal by the benzene is shown by boiling some benzene with animal charcoal, filtering off the charcoal, and using the filtrate as a solvent for the α oxime, there is no conversion into the isomer

This observation suggests that care should be exercised in the use of animal charcoal as a decolorising agent in the purification of isomers of the type of this α oxime A full account of our work on this subject will be published later elsewhere

Fluorescent and Phosphorescent Substances

SUBSTANCES which fluoresce strongly under the influence of X rays are barium and magnesium platinocyanides and cadmium tungstate The formulæ of these compounds, as given by Werner, are as follows

$$[Pt(CN)_4][Ba(H_2O)_4],$$
$$[Pt(CN)_4][Mg(H_2O)_7],$$
$$[WO_4]Cd$$

An atom of high stopping power with four light atoms or radicals arranged about it, perhaps tetrahedrally, and a bivalent positive ion, are present in all

With the first part of the formulæ may be compared the structure of zinc sulphide and diamond, which phosphoresce in X rays, phosphorus and yellow arsenic exhibit phosphorescence on oxidation, and arsenious oxide is luminous on crystallisation from acid solution

East London College,
University of London, E 1

The Medical Research Council *

IN the fifteenth annual report of the Medical Research Council, the opportunity is taken to review the progress of the past five years as well as the work of the year 1928–29 Certain changes in the composition of the Council occurred during the year the late Lord Balfour resigned the chairmanship and was succeeded by Lord D'Abernon Sir Charles Trevelyan, Prof E P Cathcart, and Sir Charles Sherrington retired, and were succeeded by Major A G Church, Prof J J R Macleod, and Mr W Trotter

The financial resources of the Council have again been augmented by donations from private benefactors and various public bodies at the same time, grants have been made to numerous workers at university and other centres of research and the laboratory facilities provided by these authorities have indirectly extended the resources of the Council In addition to appointing annually suitable workers to the Rockefeller Travelling Medical Fellowships, the Council during the past year has received a donation from Mrs Odo Cross for the endowment of research fellowships for the study of tuberculosis

The title of the Industrial Fatigue Research Board has been changed to the Industrial Health Research Board, since its investigations are now chiefly directed towards problems other than fatigue as such Among other changes in the constitution of the Board, Lord D'Abernon has retired from the chairmanship and has been succeeded by Sir Arnold Wilson

The report points out that at no time has a capital grant been made to the Council for the provision of laboratories and equipment the National Institute and the field Laboratories have been acquired and equipped out of income The former was bought in 1914 out of monies derived from non expended income in the first year of work before any awarded grants became effective during the War, the building reverted to its original use as a hospital, after the War, scientific equipment for the Institute and a freehold site of nearly 40 acres at Mill Hill were acquired out of savings accumulated during the War Further equipment has been gradually provided out of income, a laboratory building at the farm from a bequest by the late Miss O H Stubber, and during the past year a much-needed extension to the Institute from a bequest by the late Lord Justice Ronan The latter was designed to give the highest standard of hygienic conditions for the keeping of experimental animals its completion brings the National Institute as a whole, including the Farm Laboratories, to a stage of development which may be expected to provide all the main requirements for the research work centralised here for many years With the increase in accommodation provided by this extension, it has now been possible to remove the unsightly huts from the grounds of the Institute

One of the most important functions of the Council is the establishment, maintenance, and distribution of standards for certain remedies, the activity of which can only be measured by biological methods This work involves the preparation of stable standards and the determination of suitable methods of biological assay, as well as the checking of the activity of new preparations of the standard, especially in terms of an international standard, where such exists The following national standards are required to be kept at the Institute under the Therapeutic Substances Act 1927 diphtheria antitoxin, tetanus antitoxin, anti dysentery serum (Shiga), tuberculin, insulin, pituitary posterior lobe, arsenobenzene, novarsenobenzene, and sulpharsenobenzene All these are based on the international standards, of which those for tuberculin and insulin were actually prepared at the Institute The international standards now held there for maintenance and general distribution are those of insulin, sulpharsenobenzene, digitalis, and ouabain National standards for the two latter are available for distribution when any authority shall require them The only commercial products which are now regularly tested at the Institute before issue are the drugs of the arsenobenzene group, but samples of the other scheduled substances prepared by the manufacturers and assayed in terms of the standard are periodically tested to see that they fulfil the specified requirements of potency, sterility, etc

The fact that most of the research work supported by the Council is conducted in the laboratory raises the question, Is there a science of experimental medicine, of which the material for study is the human patient? Clinical research can only rarely be carried out by a practising physician his work is to diagnose the condition from which the patient is suffering and to treat it, for which he must have a wide knowledge and experience of disease The advancement of scientific knowledge cannot be his primary object The clinical research worker, on the other hand, can devote his attention to one particular disease or group of diseases, and need not maintain his knowledge and skill at concert pitch over the whole clinical field He must tend to ignore the individual patient and study the disease process as such by experimental methods, whether at the bedside or in the laboratory Again, it is clear that the teaching of general medicine is incompatible with a whole time devotion to the study of one small corner of this field It is for this reason that the clinical 'units' set up in certain teaching hospitals have been unable to carry out much research work although they have served as excellent centres for the teaching of clinical medicine

Fifteen years ago the Council set up a clinical 'research unit' at University College Hospital, London, appointing Dr (now Sir) Thomas Lewis as whole time director and providing adequate personnel and facilities for his work The success of this experiment answers the question asked

* Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the year 1928–29 (London H M Stationery Office, 1930) Price 3s net

above there is a science of experimental medicine The work of Sir Thomas Lewis and his collaborators on the heart and vascular system, its disorders and their treatment, has constituted the central stream of progress made in these subjects during the past decade For similar advances in other directions it is essential to recruit clinical research workers, but men will not be attracted without the possibility of some definite post in clinical research being available to them in the future, which is not the case at present The Council therefore proposes to increase the number of clinical workers upon its permanent staff as soon as suitably-trained candidates who have shown their aptitude for this type of research are available Meanwhile, the Council is prepared to encourage young workers to test themselves in this branch of medical research with the view of its becoming their life-work

The vascular response of the skin to injury has been further investigated during the year The vessels in the frog's tongue react to injury in the same way as those of the human skin, but do not respond to histamine A substance, probably a base of the histidine-arginine series can, however, be extracted from frog's skin which will reproduce the vascular reactions of injury not only in the frog's tongue, but also in the human skin (Grant and Jones) This result confirms the previous conclusion that the reaction to injury consists essentially in the liberation from the cells of the skin of histamine or some similar substance Similarly, the demonstration that acetylcholine can be isolated from the spleen is evidence in favour of its actual liberation in the tissues following certain kinds of nervous action, when the results of such nervous stimulus can be duplicated by the injection of acetylcholine (Dale and Dudley)

In this review it is impossible to refer to more than one or two of the other researches which have been carried out by members of the scientific staff of the Council or by independent workers helped by grants-in-aid abstracts of these researches, together with references to published papers, are given in the report Work on virus diseases has been continued the difficulty of making rapid progress is due to the fact that they cannot yet be grown on artificial media, although some will grow *in vitro* in the presence of a piece of surviving tissue The present position with regard to viruses is rather like that facing bacteriologists fifty years ago before adequate methods of microscopic study and cultivation had been worked out More progress has been made in the devising of methods of immunising animals to these diseases, and it is now possible to immunise dogs to distemper, fowls to fowl plague, and monkeys to yellow fever

Research on chemotherapeutic agents is being actively pursued certain aromatic amides containing arsenic have a pronounced curative action in some types of trypanosomiasis, as well as some new styryl compounds the latter are being tested against trypanosomiasis of cattle in Tanganyika Territory

Finally, among other subjects referred to in the report may be mentioned work on cancer and radium, anæsthetics, the vitamins, and the physiological actions of different types of light

The Deutsches Museum, Munich

THE Royal Commission on National Museums and Galleries in its Final Report, of which, as a whole, we had something to say in our issue of Feb 1 (p 153), deals with individual institutions We are particularly interested in those which are wholly or partly of a scientific character, and we notice that the Commissioners in dealing with the Science Museum direct pointed attention to the Deutsches Museum von Meisterwerken der Naturwissenschaft und Technik, to give it its full title, " not only because it is in itself a remarkable example of how a modern Museum can be made a great instrument of technical as well as of popular instruction, but because it is a symbol of national efficiency It reveals the intense concentration in the Germany of to day on the scientific means of industrial progress, a concentration which we believe has its sharp significance for this country " We are pleased, by the way, to see that the Commissioners commend to the nation the scientific attitude of mind, for it is one that we try year in and year out in these columns to inculcate

Perhaps, then, we can scarcely do greater service to our readers than to place before them a brief account of the Deutsches Museum Its aim is stated succinctly and correctly in the words of the Report to illustrate " the development of research and discovery of every age and of all countries, an Institution in which the results of scientific research and experiment should be fully shown But beyond this another purpose has been kept in view The Museum is to be a great instrument for the education of the visitor He must not only be informed by studying the exhibits as to the growth and progress of a subject, but as far as possible he must be put into a position to realize and verify, through experiments performed by himself, the steps by which the progress has been achieved " Such is the example held up to us for emulation

A short account of the Museum was published in NATURE in 1925 (Vol 115, 611), when the Museum was about to be formally opened, and it is unnecessary, therefore, to repeat the history beyond saying that the institution, contrary to what one might expect in Germany, is neither State owned nor State governed It owes its inception and management up to the present to Dr Ing Oskar von Miller, a distinguished electrical power engineer, and it is an open secret that the idea of forming a museum of this kind was implanted in his mind when, as a young man, he visited the Loan Collection of Scientific Apparatus at South Kensington in 1876 He pondered the idea for more than a quarter of a century until he felt able to put his

plans before the technical and scientific public of Germany The scheme was approved unanimously and work was at once commenced in temporary premises The permanent building, of a model of which, prepared last year, we give an illustration (Fig 1) kindly supplied by Dr von Miller, together with a ground plan (Fig 2), from the same source, is magnificently situated on an island in the River Isar, on which the city of Munich stands The Museum was opened with almost princely splendour on May 7, 1925, the seventieth birthday of the founder and director

The building is rectangular in plan, 345 feet by 325 feet, and the whole of the area on the ground floor is given up to exhibition space, side and top lighted The basement, of the same extent, is professional men received no fees, and the workmen even worked on Sundays for nothing The result is a building estimated to have cost 1½ million pounds

The Museum galleries are subdivided by partitions into spaces each sufficient for the section concerned, which is thus marked off from the rest, at the same time affording space for wall cases or diagrams In museum fittings there is no rigidity, everything seems designed to suit the particular circumstances

On the first floor over the entrance is a Hall of Fame, where memorials to the great men of science are set up This human touch is everywhere, for lesser men are commemorated in the sections where their labours are recorded On the second floor is a reading room with a supply of technical literature

Museum Building 387,504 sq ft. exhibition floor space
Library Building, with bookcases, read ing rooms, and stacks for one million volumes
Congress Hall building with accommodation for 2000 persons
Connecting building with restaurant
Connecting building with two lecture halls for 200 300 persons

Fig 1 —The Deutsches Museum, Munich

taken up partly by exhibits, partly with workshops and the necessary museum services A sub-base ment is used to set out coal, mineral, and salt mines On the first floor the building is brought to the form of a hollow rectangle with a median gallery, which in common with the two galleries parallel to it are 68 ft wide, the galleries at the ends are 57 ft wide The second, third, and fourth floors are repetitions of the first without the median gallery At the south west angle is a noble tower used for a barometer and lift At the north-east angle a fifth and a sixth floor have been built for astronomy In all there is a grand total of 387,000 sq ft of public floor space Both electric heating and lighting are supplied free by the city of Munich from a transformer station fed from the great Walchensee grid supply, in the origination of which von Miller himself was largely concerned

The way in which the building was carried out, mainly in the post-War period of financial instability, reads like a romance The aggregate for the reinforced concrete came from the bed of the river, the cement, stone, wood, and steel were given, the and there are four bookstalls There are also two refreshment rooms

'Interiors' affording a further human touch are a great feature These take a variety of forms, for example, a scythe forge of 1803 from the Black Forest, a copy of a Swiss watchmaker's shop with its hand tools, side by side with a portion of a modern factory with machine tools, for comparison, an actual paper mill of the eighteenth century, reproductions of an alchemist's and of an eighteenth century chemist's laboratory, a scriptorium with a monk copying a missal, a fine salon containing the old musical instruments, with a musician in attendance to play upon them

Interiors of a different order are the two planetaria in the Astronomy Section We need mention only the Ptolemaic one, by an optical projection apparatus images of the fixed stars of the northern hemisphere are thrown on the domed ceiling of a darkened room and the motion of the heavens during twenty-four hours can be reproduced in the space of four minutes Further, by another projection apparatus, in conjunction with gearing like an

orrery, the images of the sun, moon, and planets can be thrown on the same dome, and their motion during a whole year reproduced in five minutes The effect is thrilling and created a furore in Germany, with the result that planetaria have been installed by many of the larger cities

Since the main function of a museum as usually understood is to conserve objects, we find a great feature made of collections of original apparatus and MSS of famous workers in science The wealth of material under this head is remarkable when it is considered how loth to part with it must have been the institutions in which it had hitherto been preserved It is a tribute to von Miller that he has been able to deflect the policy, only too frequently pursued, of the 'dog in the manger'

Were there nothing further in the Museum than what we have cited above, we should describe it as an advanced institution of its kind, but little more We find, however, another feature, and the outstanding one, and that is its direct educational purpose Everywhere, and more particularly in the Physics Section which has been longest in being and is presumably most mature, the visitor finds experiments described in modern text books so arranged that he can perform them by himself or with the aid in some cases of an obliging attendant He can demonstrate natural laws and reproduce some of the more striking results of modern physics The dictum of Goethe has been acted on "Es ist nicht genug zu wissen, man muss auch thun" For example, in acoustics the gradual development of our knowledge of sound vibrations is brought out by experiment The formation of the voice, the action of the ear, the phonograph and gramophone are made clear with working models In a specially designed room are experiments to hand on the composition and resolution of musical notes In optics, again, for example, defects of vision are shown by four models of an eye viewing illuminated objects at a distance In each case the retina is transparent, and the visitor sees from behind the images of the objects projected on it The first eye is normal, by a slight adjustment of the lens in the eye the near or far distant object can be focused The second eye is short-sighted, the near object is distinct, the far object is brought into focus by interposing a concave lens The third eye is long-sighted for the near object, a convex lens has to be interposed The fourth eye is astigmatic and a cylindrical lens is required for correction Would any person after seeing this exhibit wear spectacles picked up at random ?

In aeronautics is a small working wind channel where, with the aid of an attendant, the lift and resistance of solids can be measured on sensitive direct reading balances Selected objects that have the same resistance but are very different in shape, for example, a circular disc and a model of an air ship, are tried successively In section after section one comes across similar experimental apparatus

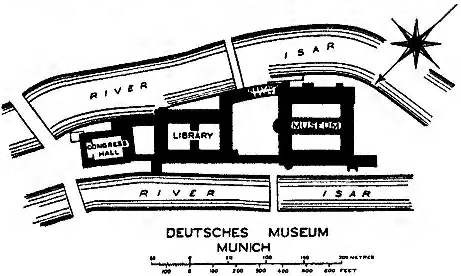

Fig 2

There are other activities that we noticed, such as the guide lectures twice daily in the galleries These are so arranged that practically the whole of the collections are covered in the week Lantern and film lectures are given in the afternoons

This, however, is far from completing the story, for von Miller had the further conception of a vast library to contain MSS and books on science, periodicals, drawings, diagrams, portraits, photographic films, lantern slides and catalogues, in fact to constitute a record office of the march of science, a storehouse of garnered knowledge and of material upon which further research can be made The Museum really only presents in an assimilable form an epitome of what will be found eventually in the Library This conception is taking shape rapidly, and the building, adjoining the Museum, yet integral with it architecturally, is being pushed on rapidly so that it may be opened next month From what has just been said it will be seen that the Library is much greater in extent than the Museum

Beyond the Library building must be mentioned the Congress Hall with accommodation for 2000 persons This is provided with arrangements for lantern, silent and sound film projection, as well as for scientific demonstrations

The building that joins the Museum to the Library has restaurant accommodation, and in the corresponding building between the Library and the Congress Hall are two lecture rooms with

accommodation for 200 300 persons, principally intended for schools and institutions

As one traverses the galleries and muses on the complexities of civilised life and how little the great bulk of our populations realise, much less understand, the nature of the network of social activities upon which their very existence depends, to say nothing of the conveniences and amusements with which they are surrounded, one cannot help thinking that wise statesmen would see to it that museums such as this should be established in every large territory and that visits to it should be part of the duties of citizenship Judging from our own reaction to the Museum, it fires the imagination, arouses the creative or inventive instinct, deepens the sense of responsibility to one's fellows and leads to a determination to add if possible to the common weal

What lessons has the Museum to teach us, particularly in regard to developing the Science Museum at South Kensington? Let us remember that it was in Great Britain three quarters of a century ago that the idea originated that a museum must not be a storehouse merely, but also a direct means of education Without slavish copying, and bearing in mind the serious limitations imposed by the nature of the present site at South Kensington, we suggest that considerable extension of the experimental apparatus should be made Further, that the human note should be sounded by paying greater attention to the lives of the great men who have left their mark on this age of ours The addition of interiors, again giving the human touch by showing man in his environment at different periods, is eminently desirable A planetarium should be installed even if the necessary large outlay —£20,000—upon it should have to be recouped by a special charge for admission

It is no use complaining of the attitude of the public towards science, that attitude can be changed for the better if we bring science to the public The success of the Science Museum, judging by the attendances since the present building was opened, shows that response is immediate

Obituary

Prof J O Arnold, F R S

PROF ARNOLD, whose death occurred on Mar 27, must be regarded as one of the founders of the modern metallurgy of steel It was largely through his efforts that the scientific control of manufacture by chemical analysis and microscopical examination has been generally adopted in the steel industry, whilst his researches have played a most important part in building up our knowledge of the constitution of the alloys of iron In both these directions he rendered great services to science in general, and to the industry of his adopted city of Sheffield in particular

John Oliver Arnold was born at Peterborough on Dec 29, 1858, his father being an engineer by profession He was educated at King Edward VI School, Birmingham, and entered the navy as a cadet, but quitted it after a voyage to India, becoming a works chemist at a time when few steel works had such men on their staff His naval experience left him with a strong love of the sea, and he remained an enthusiastic yachtsman to the end of his life, although the restrictions of the War period compelled him to leave the stormy seas of the west coast and to confine his sailing to the waters of Windermere

In 1889, after eleven years as a works chemist and consultant, Arnold was appointed professor of metallurgy in the Sheffield Technical School, and here he continued to work until his retirement through ill health in 1920, the Technical School having meanwhile become a part of the University of Sheffield, with a separate Faculty of Metallurgy, of which Arnold was appointed Dean On his retirement he was nominated emeritus professor His work during thirty-one years was intimately bound up with the progress of the Department of which he was the head, and its interests always stood first in his activities He had to create the demand for trained men in the steel industry, and his enthusiasm enabled him to achieve great success in this direction, so that he had the pleasure of seeing his old students occupying leading positions in industry, and themselves carrying out researches in his favourite science

On the scientific side, Arnold's work followed on that of Sorby, whose friend and disciple he was He became convinced of the value of Sorby's use of the microscope in the study of steel, and himself did much to perfect the technique of metallography, whilst his discoveries were made by a skilful combination of chemical and microscopical methods It is remarkable that for many years he made little use of photography in recording the structure of metals, but preferred drawings, many of which were executed with wonderful skill and patience by members of his staff He was always inclined to prefer a chemical explanation to one which depended on more obscure physical changes, as in his long controversy concerning the causes of the hardness of steel, which he maintained to be due to combination with carbon rather than to the existence of allotropic modifications of iron The two schools have become reconciled since, but it is impossible to read the earlier papers without realising that Arnold was always close to experience, and that his arguments were invariably based on practical knowledge of the behaviour of steel in the laboratory and in the works His descriptions of troostite and of what is now called martensite show a remarkable insight, although the terms in which he described the structures often seemed to differ from those in general use He also added much to our knowledge of the influence of impurities on steel

Arnold was closely connected with the development of high-speed tool steels, and in this matter he had the closest confidence of the manufacturers It was due to him that vanadium was adopted as a constituent of the highest class of such steels,

whilst his long series of papers on the carbides threw much light on the influence of alloying elements in special steels He was frequently involved in controversy, and appeared to enjoy it, his vigorous personality and his command of picturesque English lending interest to his frequent interventions in the discussions of the Iron and Steel Institute He was elected a fellow of the Royal Society in 1912, and was awarded the Bessemer medal of the Iron and Steel Institute in 1905 Of fine presence and genial manner, a good talker with a fund of humour, he was devoted to the interests of his students and was loved by them He has left a vivid impression on all who knew him, and his place in the history of metallurgy will be a high one C H D

Sir Edward Brabrook, C B

We regret to record the death of Sir Edward W Brabrook, which took place in his ninety first year at Wallington, Surrey, on Mar 20 Within the space of one week, two prominent survivors of the Victorian Age in the learned world, Edward Clodd and Edward Brabrook, passed away at an advanced age They had much in common both were men of affairs, both were interested in anthropological studies, especially folk lore, and both were members of the circle in which were Huxley, Avebury, Sir John Evans, Pitt Rivers, E B Tylor, and others upon whom in the latter half of the last century fell the burden of winning for anthropological studies an independent and recognised place in the academic and scientific world It was only in 1884 that anthropology was granted a separate section at the annual meeting of the British Association In this struggle—for it was little less—Brabrook took his full share

Edward William Brabrook was born in Cornhill, London, on April 10, 1839 He was educated at the school of Mr William Pinches, Bell Alley, Lombard Street, and then entered an insurance office, but in 1869 he was appointed Assistant Registrar of Friendly Societies Later he was called to the Bar A Civil Servant of the best type, his official career calls for little comment He was appointed Chief Registrar in 1891, and retired under the age limit in 1904, having been created C B shortly before and receiving the honour of knighthood on retirement A recognised authority on the subject of thrift, his writings on friendly societies and State insurance, and particularly his review of the progress of friendly societies down to 1914, which appeared in the *Journal of the Statistical Society*, are classics in their field, even though the author adhered to the idea of 'self-help' at a time when in practical politics the view of the responsibility of the State had ceased to be restricted by that principle

Brabrook's activities were by no means confined to his official duties Indeed, it was outside the range of those duties that he was best known and perhaps will best be remembered He was a man of many friendships, and these lay where his intellectual interests called him—in the learned world, and especially in the world of anthropology and archæology In 1860 he became a fellow of the Society of Antiquaries, and soon after the foundation of the Anthropological Society by Sir Richard Burton and George Hunt in 1863, as the result of a split in the Ethnological Society, he became the director or honorary secretary of the newly formed body He thus came to take a share in the controversies and discussions between the two divergent views on the scope and methods of anthropological science which were finally composed by the foundation of the Anthropological Institute of Great Britain and Ireland in 1871 In this, as in the many other societies he helped to found, and in the work of which he took an active part, Brabrook's position was unique By his knowledge of procedure and of the technicalities relating to associations "not trading for profit", he was able to guide them through the difficulties of their early days, while his interests over a wide field of research, combined with his abilities and experience as an administrator, made him an invaluable aid in the promotion of combined action in scientific studies which led to the publication by the British Association of "Notes and Queries on Anthropology" and to proposals for anthropological and ethnographical research in Great Britain and in the dependencies, some of which have since borne fruit, while others, unfortunately, are still the objects of desire of the anthropologists of to day

It was these qualities, as much as his scientific knowledge, which made Brabrook a valued member of the governing bodies of the Anthropological Institute, of which he was director in 1873 and president in 1895–97, of the Folk-Lore Society, founded in 1878, of which also he was president in 1901–2, of the Child Study Society, of the Eugenics Education Society, and of the Rationalist Press Association In 1898 he was president of Section H (Anthropology) of the British Association at Bristol, an occasion made notable by the appearance of de Rougemont, and in 1904 he was also president of Section F (Economic Science and Statistics) So late as 1920–21 he was president of the South Eastern Union of Scientific Societies

Apart from subjects related to his official duties, upon which he wrote three books, Brabrook's voluminous writings are, for the most part, scattered in the publications of the many societies to which he belonged, but he wrote a history of the Society of Literature, several legal treatises, and a history of the dining club of the Society of Antiquaries, of which he had long been a member

Prof Eugenio Rignano

Eugenio Rignano was born on May 31, 1870, at Livorno in Italy His education was almost wholly physical and mathematical, and after graduating from the University of Pisa he obtained full engineering qualifications in 1893 Instead of practising this profession, however, he devoted himself to philosophical studies, being particularly interested in the borderline between philosophy and science, especially biology In later life he

was appointed professor of philosophy at the University of Pavia, although he had never officially taught that subject In 1906, Rignano was able to bring into being a scheme he had long cherished, namely, the foundation of an international journal dealing with the theoretical aspects of science and its relations with other realms of human experience Under the name of *Scientia* this journal continues to flourish, and Rignano edited it himself until his death on Feb 9 last Towards the end of his life he was the recipient of numerous honours, in 1920 he was the Michonis Lecturer at the Collège de France, in 1923 he was named corresponding member of the Institute of France, and in 1926 of the Academy of Madrid

Rignano's early association with engineering conferred a quality upon all his thought and writings which they never lost Instead of constructing bridges across material ravines, he was constantly eager to bridge the gulfs which separate opposing positions in philosophy, and in this process merely destructive criticism was useless to him Invested with a pre eminently cross bench mind, he approached each new opposition with only one prejudice, namely, that in all probability both sides would be partially right Although in many cases his diagnosis of where they were wrong did not commend itself to other students, the example which he gave of creative synthesis of antinomies always merited the utmost praise

In biology Rignano's efforts were all directed to mediating between the ancient enemies of vitalism and mechanism He recognised on one hand that mysterious postulates such as the entelechy were admissions of the bankruptcy of our notions of causation, but, on the other hand, he felt that teleological considerations were too closely bound up with the phenomena of life to come unstuck, as it were, from them, even through the powerfully solvent action of the study of scientific method Final causes were not, however, interpreted by Rignano in an Aristotelian manner, that is, as existing posterior in time to the events caused, his teleology was based on a postulated mnemonic quality on living organisms, which he called 'specific accumulation' With the aid of this hypothesis, and of one or two others, such as the attribution of a separate form of energy, equivalent to heat or mechanical energy, to living systems—a form which would be transmutable into any of the others, following the principles of conservation, and yet would not be measurable since no apparatus had been devised for measuring it—Rignano constructed a complete theoretical biology 'Energetical vitalism', as he called it, bridged the gulf between the disputants by retaining what was best from each, but it cannot be said to have won general approval, and is perhaps more valuable in its example than in its essence It is fully described in Rignano's "On the Transmissibility of Acquired Characters Hypothesis of a Centro-Epigenesis", "Biological Memory", "The Finalistic Aspect of Life", "What is Life?" and "Man Not a Machine"

In other fields Rignano's passion for synthesis and the abolition of contradictions appeared equally clearly In his "Problems of the Psyche", he attempted to conciliate English 'Associationism' on one hand and German 'Gestaltism' on the other, demonstrating that at least potential activity impregnates all the manifestations of thought In his "A Socialism in accordance with Liberal Economic Doctrine" he intervened between the elementary social justice to which the socialist critic appeals and the Utopian and impractical character of collectivism and other socialist systems, in order to advocate a gradual nationalisation of private capital by means of new laws relative to the right of testation Finally, in the domain of ethics, he faced seriously the conflict between the morals of paganism and of ascetic Christianity, and in his "The Purpose of Man" proposed an ethical system founded on the harmony of life His death is a severe blow to the constructive forces in philosophy at the present day

JOSEPH NEEDHAM

MR CHARLES EDGAR SALMON, the well known systematic botanist, whose sudden death occurred on Jan 1, 1930, was born on Nov 22, 1872 He was an architect by profession and had an extensive practice in the Reigate district Salmon was essentially a field botanist with a wide knowledge of the British spermatophytic flora, to the study of which he had devoted most of his leisure time for many years A considerable number of papers in the *Journal of Botany* and elsewhere testify to his industry and the part he played in advancing the study of British flowering plants In addition, Salmon was an authority on the sea lavenders (*Limonium*), and at the time of his death was correcting the proofs of a flora of his own county of Surrey He was an active member of the Linnean Society and served on its Council from 1920 to 1923 His extensive herbarium, including part of the collections of the late Mr Arthur Bennett, has been bequeathed to the British Museum (Natural History) His many colleagues will miss, first the help he was always willing to give in identifying species of the many genera with which he had worked and, above all, a genial unselfish friend remarkable for his amiability and sense of humour W B T

WE regret to announce the following deaths

Dr Henry J Cox, senior meteorologist in charge of the north central forecasting district and corn and wheat region service of the U S Weather Bureau, on Jan 7, aged sixty six years

Sir Gordon Guggisberg, K C M G, until recently governor and commander in chief of British Guiana, formerly surveyor general of Nigeria, and author, with the Rev. A G Fraser, of "The Future of the Negro", on April 21, aged sixty years

Dr R M Pearce, director of the Division of Medical Sciences of the Rockefeller Foundation, on Feb 16, aged fifty-five years

Mr P A Ralli, chief aerodynamic expert and technical engineer for many years of the Fairey Aviation Company, who was known for his studies of air screws, on April 17, aged forty-one years.

News and Views.

Prof Smithells, the retiring president of the Institute of Chemistry, discussed in his presidential address, which has recently been published, a matter which has become one of some concern to students, to teachers, and to employers, namely, the ever increasing load put upon professional chemical students The knowledge of inorganic, organic, and physical chemistry with which the student to day is expected to equip himself, usually within a period of three academic years, forms in its content of fact and charge on the memory a burden which Prof Smithells estimates to have nearly doubled during his own experience Whilst willing to admit that the capacity of succeeding generations expands, he does not believe that in such a brief period of human evolution the powers of apprehension or of memory have become doubled, he therefore anticipates that, as a result, there will be undigested knowledge of what are thought to be the higher things of chemical science, and, worse still, a superficial knowledge or entire ignorance of simpler things

Prof Smithells' own experience of the results derived from modern chemical curricula will find support in the experience of many of his professional colleagues both within and outside university chemical departments, and students themselves would be the first to admit that the width and depth of the studies now required of them in preparation for a first degree leave little opportunity for independent thought or for the free culture of the chemical arts Pressure similarly falls upon their instructors, who are too frequently condemned to spend their time term by term doling out partially predigested and ever growing masses of fact and theory in the hope that an adequate proportion will be retained long enough for examination purposes Specialist instruction properly finds its place in modern teaching institutions It is, of course, their function to disseminate what is erudite as well as what is simple and fundamental, to test all kinds of facts and theories, and to advance knowledge in every branch of learning Prof Smithells insists, however, that there is a limit to what may be rightly imported from new provinces into the common stock of what purports to be general chemical training In his experience a teacher reluctantly jettisons old cargo to make room for new, and since at the same time the last charge he would wish to lie against him is that of not keeping up with the times, the courses tend to become overloaded, the pace too great, and the foundation ill laid

Prof Smithells thinks that we have unwittingly allowed a good deal to come into our general courses of instruction that should be left for a subsequent period of specialisation In pleading for a slackening of the pace, he feels that we are sacrificing not so much any particular kind of knowledge as the conditions under which sound knowledge can be acquired He is, however, speaking of the training of professional chemists whose national responsibilities will in due time be so much greater than formerly, whose capacity will determine in no small measure the industrial future of their country Hence we would wish that Prof Smithells had laid greater emphasis on his statement that the young chemist is now often not kept long enough or exercised sufficiently in the wider territory of the science At least as long a road must be travelled whether the pace is moderated or not Students differ widely in their ability to assimilate what is presented to their minds and to their memories, but on the whole we feel that a case for such moderation has been made out If the sound fundamental training in the science, involving as it must do the basic principles of the most recent achievements as well as the older philosophy, cannot be acquired in three years, extension of the course for a first degree would be preferable to contraction of the field of vision

Nomenclature in chemistry is so devised as to reflect constitution and behaviour as concisely and as accurately as possible Among the more or less unsatisfactory names which chemists have inherited from an earlier age is the word 'chemist' itself, not that it does not describe concisely and accurately one who, in the definition employed by the "Encyclopædia Britannica", "for pleasure or profit concerns himself with the acquisition of information relating to the composition of bodies and the changes of composition which they undergo" The dissatisfaction arises from the fact that the law of England says that it means something quite different The use of the title by anyone who is not a registered pharmacist is, indeed, an offence, being prohibited generally by the Pharmacy Act, 1868 The prohibition is not, of course, enforced, but is for that matter none the more seemly None will deny that it is essential that the public should be protected, and proper that the profession of pharmacy should be closed to all but properly qualified persons—if need be by the grant of an exclusive title It is mentioned in a recent issue of the *Journal and Proceedings of the Institute of Chemistry* that representations were made on the subject to the Departmental Committee on the Poisons and Pharmacy Acts The Report of that Committee shows that the continuance of the anomaly is considered to be undesirable Pharmacists raise no objection to the use of the title 'chemist' by certain qualified, though unregistered, persons, except in connexion with a retail business The relinquishment of the title (in favour, for example, of 'pharmacist') by registered pharmacists was, however, considered to be impracticable from the point of view both of the expense involved in the alteration of signs and fascias, and of the popular connotation of the word itself

At his death in 1880, Frank Buckland left to the nation his Museum of Fish Culture, which is now at South Kensington, and a reversionary sum of £5000 with which to endow a professorship of economic fish culture The first fruits of this Buckland Foundation

were recently reaped when Prof W Garstang, of the University of Leeds, as Buckland professor for 1930, delivered the first course of fisheries lectures at Grimsby and Hull, an abstract of which appears elsewhere in this issue Remembering Prof Garstang's pioneer work in the transplantation of plaice from the nurseries off the coast of Europe to the rich feeding grounds of the Dogger Bank, it is singularly appropriate that he should have been chosen as the first to remind us of the life and work of Buckland, who early envisaged the 'farming' of the seas, just as the agriculturist farms the land One wonders what action Buckland would have advocated had he possessed the knowledge which has been acquired since his death and forms the subject matter of Prof Garstang's later lectures Would he have agreed with Prof Garstang that the solution of the plaice problem in the North Sea lies in transplanting every year some millions of the small, over crowded, and slow growing fish from the coastal banks to the Dogger? Furthermore, having agreed, would his great personal assets of earnestness and imperturbable humour, so helpful in negotiations, have enabled him to induce the traditional enterprise of the great Humber fishing ports to take up the matter of transplantation as a commercial proposition? Whatever the answers to these questions may be, the annual Buckland lectures will keep fresh the memory of a life devoted to the turning of natural history into practical channels, and will perform an additional service in indicating current progress towards the ideal of a rational exploitation of the resources of the sea

THOSE who, knowing the range of Prof P Debye's interests, and his remarkable linguistic powers, attended the Guthrie lecture of the Physical Society delivered by him on April 11 in the expectation of hearing original views delivered freshly and vigorously, were not disappointed Prof Debye has left his mark on modern science at many points, and it may be said of him with more truth than is to be found in most eulogiums, *nullum tetigit quod non ornavit* The debt of the chemist to him is a specially heavy one The theory of strong electrolytes was ever a difficulty until he took the matter in hand, and now his researches on X ray scattering promise equally to smooth the path of the organic chemist The scattering of X rays by the vapour of carbon tetrachloride and allied compounds formed the main part of Prof Debye's discourse An elementary investigation in which the effect of the carbon atom is neglected in comparison with that of the more massive chlorine atoms (considered as points) leads to an expectation of maxima of intensity in certain angular directions, which is confirmed by experiment A closer approximation may be made by taking into account the dimensions of the atoms, and the distance between the atoms calculated from observation of these maxima is in good accord with values obtained by independent methods More remarkable even, as illustrating the agreement between two quite independent arguments, are the results deduced from experiments made on *cis* and *trans* compounds Here the different distances between the chlorine atoms in the two forms as given by the structural formulæ of the organic chemist are faithfully reflected in the distances calculated from the results of Prof Debye's experiments If any one lesson may be drawn from his discourse, it is that the sciences cannot live in water tight compartments, and that organic chemistry in particular needs all the assistance that modern mathematics and physics can give The address, delivered in fluent and idiomatic English, was most happily balanced in its account of theory and experiment, and will live long in the memories of those who were privileged to attend it

AT the annual meeting of the East African Section of the London Chamber of Commerce on Mar 19, several matters of importance were dealt with A start has now been made with aerial surveys in East Africa, a subject to which the Section has devoted much attention during the last year or two, and it is probably largely through its efforts that the survey of Rhodesia has been decided on, for which purpose Mr Butler, chairman of the Aircraft Operating Co, left Heston on Mar 20 in a large Gloster biplane of new type for the aerial survey of 63,000 sq miles in Rhodesia It is hoped that other similar surveys will shortly be made in East Africa, for, as already pointed out in a memorandum which the Section submitted to the Council of the London Chamber of Commerce, such surveys are of the utmost value to a new and progressive country They are much more comprehensive and rapid than those on land, and are especially useful in connexion with the mapping out of routes for new roads and railways, of areas suitable for intensive development, forests, river courses, and much else The cost of these surveys could be looked upon as capital charge, and could doubtless be met from loans either under the East African Guaranteed Loan Act of 1926, or under the Colonial Development Act

ROAD and rail construction in British East Africa is likely to demand close attention in the near future The Council of the London Chamber has already adopted a recommendation from the Section that the Government should set up an Imperial Committee to study road transport in Central Africa (Rhodesia to the Sudan) and to make definite proposals for the construction and financing of a satisfactory road and bridge system The Prime Minister promised to give the matter earnest consideration, and it was further considered at a special meeting last October when various technical experts were present It is suggested that the vast areas in East Africa can only be opened up adequately by a carefully designed road system as an adjunct to the railway system, and so far little attention has been given to roads especially in Kenya and Tanganyika There have been several complaints as to the roads in Kenya of late, and the recent floods in Tanganyika have of course played havoc with the road system in that country According to the *East African Standard*, Mr G H Moore, Director of Roads, etc, in Kenya, and also other authorities, are giving the matter very close attention, and the possibility of a loan for a large programme of road construction is under discussion

At the general meeting of the Rubber Growers' Association (Inc) on April 11, the chairman, Mr G H Masefield, gave the following figures regarding the use of rubber in recent years The absorption of crude rubber during 1920 was 310,000 tons, of which the United States used 215,000 tons and the rest of the world 95,000 tons By 1925, these three totals were 435,000, 315,000, and 120,000 tons respectively, while by 1929 the corresponding figures were 785,000, 470,000, and 315,000 tons During the last nine years, he said, the world consumption has increased by 153 per cent, the consumption of the United States by 119 per cent, and that of other countries by 232 per cent The Association, the constituent companies of which control 1,812,000 acres planted or interplanted with rubber, takes an active part in the work of scientific research in Malaya, Ceylon, South India, and in the Netherland East Indies, and, said Mr Masefield, "There can be no question that research work will become an increasingly important factor in the future, and it will be to the scientists that we must look if we are to avoid and combat the dangers that are likely to threaten the industry when we face on the one hand huge areas of plantations run on scientific lines, and on the other an almost equal area of rubber planted haphazard in small holdings on which disease in many cases is likely to become completely out of hand"

It is announced that the Second International Congress of the History of Science and Technology is to be held in London in July 1931 These congresses take place biennially and are organised by Le Comité International d'Histoire des Sciences, which was founded at Oslo on Aug 17, 1928, and the permanent secretary of which is Prof Aldo Mieli The aim of the Congress is to provide opportunity for intercourse and exchange of thought between all those who are interested in any aspect of the history of science and technology The co operation of the three international societies which cover this field of learning, namely, the History of Science Society, the Newcomen Society for the Study of the History of Engineering and Technology, and Le Comité International des Sciences Historiques, has already been assured A number of influential men of science are giving their support, and a council is now being formed to further the aims of the Congress A programme is being arranged to cover a period of five days, during which scientific communications will be received, visits to places of historic interest will be made, and social gatherings will be held The headquarters of the Congress is at the Science Museum, South Kensington, S W 7, the honorary secretary is Mr H W Dickinson, from whom further particulars can be obtained

The establishment, on the recommendation of the U S National Academy of Sciences, of the new Woods Hole Oceanographical Institution is of much interest and importance Its purpose is to carry on and encourage the study of the sea in the broadest sense, and funds from the Rockefeller Foundation are available for the building and for a sufficient operating income It is, like the Marine Biological Laboratory at Plymouth in Great Britain, an independent organisation, but similarly assured of informal association with other educational and research institutions through its trustees The initial board includes many well known names, with Dr Henry R Bigelow as director and Dr Frank Lillie as president After careful consideration, Woods Hole was chosen as the site of the new Institution, the principal reasons being its proximity to the famous marine biological laboratories and its extremely favourable position with regard to the neighbouring waters Some of the most productive fisheries can be reached in a few hours, and the variety of conditions is unparalleled It is planned to have a sea-going ship equipped for scientific investigations in all fields of oceanography, capable of extended voyages, to be in commission throughout the year, and to have a resident staff for the laboratory Plans are already in preparation, and it is hoped that the Institution will be ready to open by the summer of 1931 Meanwhile, the trustees will announce the plans for research based on the general principle of offering opportunities to visitors from America or from other countries, especially for work at sea, and for them to co-operate with the staff in a general programme of oceanographical research, besides giving every facility to individual workers on shore It is hoped also to offer instruction to university students in oceanographical methods both at sea and in the laboratory. This institution will be a welcome addition to the resources of oceanographical studies

The gorilla expedition, organised under the joint auspices of the Carnegie Institution of Washington and Yale University, which set out last June for Central Africa, has completed its work, and a summary of results has been issued by the Carnegie Institution Dr. Harold C Bingham and his wife reached the Belgian gorilla reservation in the Kivu region early in August and commenced work at the spot where Carl Akeley died in 1926 They were frequently in contact with various gorilla groups, following them as they fed their way along, carefully recording, for future study, observations on the nests, the feeding habits, the social responses, the nomadic behaviour, and the individual traits of the animals They took moving and still pictures whenever conditions favoured The mountain gorilla of this region inhabits the slopes of volcanic peaks at an altitude of 8000 to 12,000 ft, and it is especially in the bamboo belt of the dense forest and for a considerable distance above it, that the gorilla ranges in search of food This consists mainly of the succulent 'suckers' sent up by the bamboo roots, and of a luxuriant 'wild celery' which attains a height of six to eight feet over extensive areas

Doubt has been expressed regarding the nesting habits of the mountain gorilla, some reports stating that nests are constructed in trees, while others allege that they are never built off the ground Dr and Mrs Bingham undoubtedly found, in and below the bamboo belt, that tree nests were built, sometimes as high as fifty feet above ground, and they also found old nests of chimpanzees The gorilla nests were very simple

affairs, usually made by pulling and breaking down the plants and vines which chanced to be at hand They gave evidence of being occupied only for a single night during the perpetual wanderings of the gorilla bands But the explorers are cautious about dogmatising concerning the position of the nests, and suggest that the varying physical conditions in the areas over which the gorillas range may lead to important differences in feeding and nesting habits They think it probable that changes in climate, in seasons, in rainfall, in temperature, possibly also changes in air currents and the like, may affect the behaviour of the gorillas so that they exhibit significant environmental adaptations

RUGBY School Natural History Society, as the *Report* for 1929 shows, has greatly increased its adherents by the introduction of popular lectures and exhibits of kinematograph films On the other hand, the attendances at the specialised sections has fallen off and many of the reports of the secretaries show a very great lack of interest on the part of members in lectures and even open air excursions The contrast suggests that it may be mistaken policy to form highly specialised sections (there are twelve in the school) the efforts of which must appeal strongly to very few boys Boys will have hobbies, and hobbies are to be encouraged but the place of a school natural history society is not to intensify the notion of specialism and sectionalism, but to keep in the forefront the idea of scientific unity, and to encourage at the school stage the widest possible acquaintance with the various aspects of scientific truth

COMPARISONS may be instructive, and the Report of the Marlborough College Natural History Society for 1929 has just been received The Natural History Society here has also its sections, but there are five only, and the enthusiasm of the members is evident Not only have the sections been well supplied with lectures, but the original records and observations in the ornithological, entomological, and botanical groups cover many pages More than half the Report (of 120 pages) contains excellent articles dealing mainly with local matters of scientific interest and including a list of the microlepidoptera of the district compiled from the Society's records, a good list of 677 species From the miscellaneous notes we learn that the grey squirrel has made its appearance in the neighbourhood

IN the course of a Lucknow University Extension lecture on Nov 15, 1929, on the interpretation of the Raman effect, a copy of which has reached us, Mr Satyendra Ray put forward a novel point of view He looks on the Raman lines as related to an effect which he calls the Bhar effect—namely, that the position of a line in a spectrogram depends upon the intensity of the source, which is taken to prove that the velocity of light is not constant, but depends upon the amplitude, analogously with sound In experiments on this effect made in 1925 by Mr Ray using rhodamine solution to weaken the *D* lines by absorption and so vary the effective amplitude of the source, the *D* lines shifted different amounts for different concentrations of the rhodamine solution, and for certain critical densities gave rise to a continuous band This is taken to be connected with the Raman effect, and particular attention is directed to the continuous spectrum often found in Raman spectra Mr Ray believes that a classical dynamical interpretation of the Raman effect can be made if it is recognised that the velocity of light is variable, that transformations of frequency are possible, and that combination tones are possible, whether differential or summational

THE Ordnance Survey has tried the experiment of issuing certain sheets of the maps of Great Britain on a tough waterproof paper This paper is not merely coated with a waterproof solution but is also impregnated after printing by a process which, it is claimed, renders it absolutely waterproof and washable, and gives it a parchment like appearance These claims appear to be justified The paper is unaffected by water and after crumpling can be ironed flat Efforts to injure our review copy by any usage to which a map might probably be subjected in the field, failed to make any notable impression The colour and legibility of the map are fully as good as the usual sheets The map is not thicker than the paper edition mounted on linen Undoubtedly this innovation should prove a blessing to those who need to use maps in the open in all weathers The sheets at present available are the "Tourist" 1 inch sheet of the Middle Thames, several of the "Popular" 1 in sheets, including some in the Midlands, Surrey, Kent, and Perthshire, and sheet No 8 of the quarter inch map of England and Wales The prices are those of the ordinary edition linen mounted and cut into sections

AN announcement of the highest importance to museums in Great Britain is made in the April number of the *Museums Journal* The Trustees of the Carnegie United Kingdom Trust have already shown in the Report issued under their auspices their interest in the progress of the museum movement As a sequel to that Report they have now announced a practical move to test its conclusions This limited preliminary experiment is to be carried out in collaboration with the Museums Association, is to cover the five years 1931–35, and is to involve an expenditure of £10,000 The money is to be allocated under a threefold scheme In the first place, £7000 is to be devoted, in grants of not more than £250 each, to public museum authorities who are prepared to adopt some definite policy and to reorganise their institutions on the lines recommended by Sir Henry Miers in his 1928 Report to the Trustees The grants are to be confined to towns with between 10,000 and 70,000 inhabitants, may be used for capital expenditure only, will not be available for building purposes, and will probably be offered on a £ for £ basis

A FURTHER move on the part of the Trustees of the Carnegie United Kingdom Trust is the offer of £3000 for the training of curators, but since the Museums Association is already negotiating with the national museums in London for an experimental school there, the Trustees will take no action until the result of this experiment has been considered In the third place, the Trustees, after their experience in connexion with the co-operative library service in rural areas, believe that some similar scheme might be the subject of a
